

BOUNDS IN COHEN'S IDEMPOTENT THEOREM

TOM SANDERS

ABSTRACT. Suppose that G is a finite Abelian group and write $\mathcal{W}(G)$ for the set of cosets of subgroups of G . We show that if $f : G \rightarrow \mathbb{Z}$ has $\|f\|_{A(G)} \leq M$ then there is some $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ such that

$$f = \sum_{W \in \mathcal{W}(G)} z(W)1_W \text{ and } \|z\|_{\ell_1(\mathcal{W}(G))} = \exp(M^{4+o(1)}).$$

1. INTRODUCTION

This paper is about quantitative aspects of Cohen's idempotent theorem, [Coh60, Theorem 3] (see also [Rud90, Theorem 3.1.3]). To state this we shall need some notation and basic results. For background we refer the reader to Rudin's book [Rud90].

Suppose, as we shall throughout the paper, that G is a finite Abelian group. We write \hat{G} for its dual group, that is the finite Abelian group of homomorphisms $G \rightarrow S^1$ where $S^1 := \{z \in \mathbb{C} : |z| = 1\}$. We regard G as endowed with a Haar probability measure m_G so that we can then define the Fourier transform of a function $f \in L_1(m_G)$ to be

$$\hat{f} : \hat{G} \rightarrow \mathbb{C}; \gamma \mapsto \int f(x) \overline{\gamma(x)} dm_G(x).$$

We shall be interested in the Wiener norm of functions, and this is defined by

$$\|f\|_{A(G)} := \|\hat{f}\|_{\ell_1(\hat{G})} = \sum_{\gamma} |\hat{f}(\gamma)|.$$

It is an easy calculation to see that if $H \leq G$ then

$$\widehat{1_H}(\gamma) = \begin{cases} m_G(H) & \text{if } \gamma(h) = 1 \text{ for all } h \in H \\ 0 & \text{otherwise,} \end{cases}$$

and it follows from this and Parseval's theorem (see (6.1) in §6 if unfamiliar) that

$$\|1_H\|_{A(G)} = \sum_{\gamma \in \hat{G}} |\widehat{1_H}(\gamma)| = \frac{1}{m_G(H)} \sum_{\gamma \in \hat{G}} |\widehat{1_H}(\gamma)|^2 = \frac{1}{m_G(H)} \int 1_H^2 dm_G = 1.$$

Writing $\mathcal{W}(G) := \bigcup \{G/H : H \leq G\}$ we see that if $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ then

$$f := \sum_{W \in \mathcal{W}(G)} z(W)1_W$$

has

$$\text{Im } f \subset \mathbb{Z} \text{ and } \|f\|_{A(G)} \leq \|z\|_{\ell_1(\mathcal{W}(G))}.$$

Our main result is the following weak converse.

Theorem 1.1. *Suppose that G is a finite Abelian group and $f : G \rightarrow \mathbb{Z}$. Then there is some $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ such that*

$$f = \sum_{W \in \mathcal{W}(G)} z(W) 1_W \text{ and } \|z\|_{\ell_1(\mathcal{W}(G))} \leq \exp(\|f\|_{A(G)}^{4+o(1)}).$$

This improves on [GS08, Theorem 1.3] where the bound on $\|z\|_{\ell_1(\mathcal{W}(G))}$ is of the form $\exp(\exp(O(\|f\|_{A(G)}^4)))$.

By considering an arithmetic progression of length $\exp(\Omega(M))$ in the group $\mathbb{Z}/p\mathbb{Z}$ for p a sufficiently large (in terms of M) prime it can be seen that there are functions $f : G \rightarrow \mathbb{Z}$ with $\|f\|_{A(G)} \leq M$ where any representation of the described form must have $\|z\|_{\ell_1(\mathcal{W}(G))} = \exp(\Omega(M))$ so that up to the power of $\|f\|_{A(G)}$ our result is best possible.

Before moving on to the rest of the paper we should discuss the structure and notation, and a little about the contribution. The overarching structure is the same as that of [GS08]. In §2, §3, §4, §5 and §6, we set up the basic background theory we shall need which is for much the same purpose as in [GS08]. Notation and definitions are setup and made as needed. In particular, the two different types of covering number we use are defined in §2; Bohr sets and their various types of dimension are defined in §3; notation for measures and convolutions at the start of §4; and approximate annihilators at the start of §5.

There were three main parts to the argument in [GS08], and essentially the first two of them introduce a need for a doubly (rather than singly) exponential bound in [GS08, Theorem 1.3]. The contribution of this paper is to note how these can be removed.

The first part of the argument in [GS08] was a sort of quantitative continuity result developed from the work of Green and Konyagin in [GK09]. Our analogue of this is in §7 and is closely related to their work, although here we make use of an advance due to Croot, Sisask and Łaba [CLS11] to get a sort of L_p version.

The second ingredient was a Freĭman-type theorem. Freĭman's theorem has been improved in recent years to have quasi-polynomial dependencies and our work simply takes advantage of this. We record a suitable Freĭman-type theorem in §8.

The third ingredient is the concept of arithmetic connectivity. We refine this in §9, but the improvement it leads to is polynomial rather than exponential. (Without any change to the notion of arithmetic connectivity from [GS08] our arguments lead to Theorem 1.1 with the $4 + o(1)$ replaced by some larger constant.)

These three main ingredients are combined in the argument in §10 to give Theorem 10.1 which has Theorem 1.1 as a special case. We finish with a concluding section in §11.

Finally, as with the argument in [GS08], though for different reasons, the argument for Theorem 1.1 has two separate points, both of which force bounds of the shape we get. The first point is in Proposition 7.1, the core of which goes back to Green and Konyagin [GK09]. Whilst we improve one dependency, the other dependencies have not been touched since their work.

The second point is in Proposition 8.1. Here there is a well-known conjectural improvement however, it doesn't seem like such an improvement is altogether necessary. In particular, it seems quite realistic to hope to improve Lemma 9.1 directly.

2. COVERING NUMBERS

Given two sets $S, T \subset G$ with T non-empty, the **covering number** of S by T is

$$\mathcal{C}_G(S; T) := \min \{|X| : S \subset X + T\}.$$

We often omit the subscript if the underlying group is clear.

Since T is non-empty and G is finite this minimum is well-defined. Moreover, if S is also non-empty then $\mathcal{C}(S; T) \geq 1$ whatever the set T .

Covering numbers enjoy the following simple properties.

Lemma 2.1 (Behaviour of covering numbers). *Suppose that G and H are Abelian groups.*

(i) (Restrictions and extensions) *For all $U \supset S$ and $T \supset V \neq \emptyset$ we have*

$$\mathcal{C}(S; T) \leq \mathcal{C}(U; V).$$

(ii) (Products) *For all $S, T \subset G$ and $U, V \subset H$ with $T, V \neq \emptyset$ we have*

$$\mathcal{C}_{G \times H}(S \times U; T \times V) \leq \mathcal{C}_G(S; T) \mathcal{C}_H(U; V).$$

(iii) (Compositions) *For all S, T, U with $T, U \neq \emptyset$ we have*

$$\mathcal{C}(S; U) \leq \mathcal{C}(S; T) \mathcal{C}(T; U).$$

(iv) (Pullbacks) *For all $U, V \subset H$ with $V \neq \emptyset$ and homomorphisms $\phi : G \rightarrow H$ we have*

$$\mathcal{C}_G(\phi^{-1}(U); \phi^{-1}(V - V)) \leq \mathcal{C}_H(U; V).$$

Proof. First, if $U \subset X + V$ and $U \supset S$ and $T \supset V$ then certainly $S \subset X + T$ from which (i) follows.

Secondly, if $S \subset X + T$ and $U \subset Y + V$ then $S \times U \subset X \times Y + T \times V$ and (ii) follows.

Thirdly, if $S \subset X + T$ and $T \subset Y + U$ then $S \subset X + Y + U$ and hence $\mathcal{C}(S, U) \leq |X + Y| \leq |X||Y|$ from which (iii) follows.

Finally, if $U \subset X + V$ then write X' for the set of $x \in X$ such that $(x + V) \cap \phi(G) \neq \emptyset$ and let $z : X' \rightarrow G$ be a choice function such that $\phi(z(x)) \in x + V$. Put $Z := \{z(x) : x \in X'\}$. If $y \in \phi^{-1}(U)$ then

$$\phi(y) \in (X + V) \cap \phi(G) \subset X' + V \subset \phi(Z) - V + V.$$

It follows that $y \in Z + \phi^{-1}(V - V)$ and we have (iv) since $|Z| \leq |X'| \leq |X|$. \square

Covering numbers are closely related to doubling as the following lemma captures.

Lemma 2.2. *Suppose that $A, B, S, T \subset G$ with $B, T \neq \emptyset$. Then*

$$m_G(A + S) \leq \mathcal{C}(A; B) \mathcal{C}(S; T) m_G(B + T).$$

Proof. Let X be such that $A \subset X + B$ and $|X| = \mathcal{C}(A, B)$, and Y be such that $S \subset Y + T$ and $|Y| = \mathcal{C}(S, T)$. Then $A + S \subset X + Y + B + T$ and hence

$$m_G(A + S) \leq m_G(X + Y + B + T) \leq |X||Y|m_G(B + T) \leq \mathcal{C}(A, B)\mathcal{C}(S, T)m_G(B + T),$$

and the lemma is proved. \square

Conversely we have Ruzsa's covering lemma.

Lemma 2.3 (Ruzsa's covering lemma). *Suppose that $A, B \subset G$ for some $B \neq \emptyset$. Then*

$$\mathcal{C}(A; B - B) \leq \frac{m_G(A + B)}{m_G(B)}.$$

Proof. Suppose that $X \subset A$ is a maximal such that for every $x, x' \in X$ if $(x + B) \cap (x' + B) \neq \emptyset$. It then follows that if $x \in A \setminus X$, there is some $x' \in X$ such that $(x + B) \cap (x' + B) \neq \emptyset$, and hence $A \setminus X \subset X + B - B$. Of course, since $0_G \in B - B$ we certainly have $X \subset X + B - B$ and so $A \subset X + B - B$. On the other hand, the sets $\{x + B : x \in X\}$ are disjoint subsets of $A + B$ and there are $|X|$ of them. The lemma follows. \square

In the light of Lemma 2.1 part (iv) above, for sets $S, T \subset G$ with $0_G \in T$ it is natural to define the **difference covering number** of S by T to be

$$\mathcal{C}_G^\Delta(S; T) := \min \{ \mathcal{C}_H(U; V) : H \in \mathbf{Ab}, \phi \in \text{Hom}(G, H), S \subset \phi^{-1}(U), \phi^{-1}(V - V) \subset T \},$$

where \mathbf{Ab} denotes the category of Abelian groups and $\text{Hom}(G, H)$ is the set of homomorphisms between G and H . As before we often omit the subscript if the underlying group is clear.

Again, since $0_G \in T$ the minimum above is well-defined, and if S is non-empty then $\mathcal{C}_G^\Delta(S; T) \geq 1$.

For our purposes difference covering numbers turn out to behave slightly better than covering numbers.

Lemma 2.4 (Behaviour of difference covering numbers).

(i) (Restrictions and extensions) *For all $S' \supset S$ and $T \supset T' \ni 0_G$ we have*

$$\mathcal{C}^\Delta(S; T) \leq \mathcal{C}^\Delta(S'; T').$$

(ii) (Intersections) *For all S, S', T, T' with $T, T' \ni 0_G$ we have*

$$\mathcal{C}^\Delta(S \cap S'; T \cap T') \leq \mathcal{C}^\Delta(S; T) \mathcal{C}^\Delta(S'; T').$$

(iii) (Domination by coverings numbers) *For all S, T with $T \ni 0_G$ we have*

$$\mathcal{C}^\Delta(S; T - T) \leq \mathcal{C}(S; T).$$

(iv) (Domination of coverings numbers) *For all S, T with $T \ni 0_G$ we have*

$$\mathcal{C}(S; T) \leq \mathcal{C}^\Delta(S; T).$$

Proof. First, (i) follows immediately from the definition of the difference covering number.

Secondly, suppose that $\phi \in \text{Hom}(G, H)$ and $\psi \in \text{Hom}(G, H')$, and $U, V \subset H$ have $\mathcal{C}_H(U; V) = \mathcal{C}_G^\Delta(S; T)$ and $U', V' \subset H$ have $\mathcal{C}_{H'}(U'; V') = \mathcal{C}_G^\Delta(S'; T')$, are all such that

$$S \subset \phi^{-1}(U), \phi^{-1}(V - V) \subset T, S' \subset \psi^{-1}(U'), \text{ and } \psi^{-1}(V' - V') \subset T'.$$

The map $\phi \times \psi$ is a group homomorphism $G \rightarrow H \times H'$ (defined by $x \mapsto (\phi(x), \psi(x))$). Moreover,

$$S \cap S' \subset \phi^{-1}(U) \cap \psi^{-1}(U') = (\phi \times \psi)^{-1}(U \times U')$$

and

$$\begin{aligned} (\phi \times \psi)^{-1}(V \times V' - V \times V') &= (\phi \times \psi)^{-1}((V - V) \times (V' - V')) \\ &= \phi^{-1}(V - V) \cap \psi^{-1}(V' - V') \subset T \cap T'. \end{aligned}$$

By the definition of the difference covering number and Lemma 2.1 (ii) we have that

$$\begin{aligned} \mathcal{C}_G^\Delta(S \cap S'; T \cap T') &\leq \mathcal{C}_{H \times H'}(U \times U'; V \times V') \\ &= \mathcal{C}_H(U; V) \mathcal{C}_{H'}(U'; V') = \mathcal{C}_G^\Delta(S; T) \mathcal{C}_G^\Delta(S'; T'). \end{aligned}$$

Part (ii) is proved.

Thirdly, let $\phi : G \rightarrow G$ be the identity homomorphism, $U := S$ and $V := T$ so that $S \subset \phi^{-1}(U)$ and $\phi^{-1}(V - V) \subset T - T$. It follows that

$$\mathcal{C}_G^\Delta(S; T - T) \leq \mathcal{C}_G(U; V) = \mathcal{C}_G(S; T)$$

and (iii) is proved.

Finally, let $\phi \in \text{Hom}(G, H)$ and $U, V \subset H$ be such that $S \subset \phi^{-1}(U)$ and $\phi^{-1}(V - V) \subset T$ and $\mathcal{C}_H(U; V) = \mathcal{C}_G^\Delta(S; T)$. Then by Lemma 2.1 (i) and (iv) we see that

$$\mathcal{C}_G(S; T) \leq \mathcal{C}_G(\phi^{-1}(U); \phi^{-1}(V - V)) \leq \mathcal{C}_H(U; V) = \mathcal{C}_G^\Delta(S; T).$$

This gives (iv). \square

It will also be useful to have a version of Ruzsa's covering lemma for difference covering numbers.

Lemma 2.5 (Ruzsa's covering lemma, revisited). *Suppose that $A, B, X \subset G$ with both $X \neq \emptyset$ and $0_G \in B$. Then*

$$\mathcal{C}^\Delta(A; B) \leq \frac{m_G(A + X)}{m_G(X)} \mathcal{C}^\Delta(X - X; B).$$

Proof. Let H be an Abelian group, $\phi \in \text{Hom}(G, H)$ and $U, V \subset H$ be such that $\phi^{-1}(U) \supset X - X$ and $\phi^{-1}(V - V) \subset B$. By Ruzsa's covering lemma (Lemma 2.3) we see that there is some set T with

$$|T| \leq \frac{m_G(A + X)}{m_G(X)} \text{ and } A \subset T + X - X.$$

Let $U' := \phi(T) + U$ so that $\mathcal{C}_H(U'; V) \leq |T| \mathcal{C}_H(U; V)$. On the other hand $\phi^{-1}(U') \supset T + X - X \supset A$ and the result follows. \square

3. BOHR SYSTEMS

Bohr sets interact particularly well with covering numbers and difference covering numbers. We write $\|\cdot\|$ for the map $S^1 \rightarrow [0, \frac{1}{2}]$ defined by

$$\|z\| := \min\{|\theta| : z = \exp(2\pi i\theta)\}.$$

It is easy to check that this is well-defined and that the map $(z, w) \mapsto \|zw^{-1}\|$ is a translation-invariant metric on S^1 . Given a set of characters Γ on G , and a function $\delta : \Gamma \rightarrow \mathbb{R}_{>0}$, then we write

$$\text{Bohr}(\Gamma, \delta) := \{x \in G : \|\gamma(x)\| < \delta(\gamma) \text{ for all } \gamma \in \Gamma\},$$

and call such a set a (generalised¹) **Bohr set**.

In fact we shall not so much be interested in Bohr sets as *families* of Bohr sets. A **Bohr system** is a vector $B = (B_\eta)_{\eta \in (0,1]}$ for which there is a set of characters Γ and a function $\delta : \Gamma \rightarrow \mathbb{R}_{>0}$ such that

$$B_\eta = \text{Bohr}(\Gamma, \eta\delta) \text{ for each } \eta \in (0, 1].$$

We say that B is **generated** by (Γ, δ) and, of course, the same Bohr system may be generated by different pairs.

This definition is motivated by that of Bourgain systems [GS08, Definition 4.1], although it is in some sense ‘smoother’. (In this paper what we mean by this is captured by Lemma 3.4 which does not hold for Bourgain systems.)

We first record some trivial properties of Bohr systems; their proof is left to the reader.

Lemma 3.1 (Properties of Bohr systems). *Suppose that B is a Bohr system. Then*

- (i) (Identity) $0_G \in B_\eta$ for all $\eta \in (0, 1]$;
- (ii) (Symmetry) $B_\eta = -B_\eta$ for all $\eta \in (0, 1]$;
- (iii) (Nesting) $B_\eta \subset B_{\eta'}$ whenever $0 < \eta \leq \eta' \leq 1$;
- (iv) (Sub-additivity) $B_\eta + B_{\eta'} \subset B_{\eta+\eta'}$ for all $\eta, \eta' \in (0, 1]$ with $\eta + \eta' \leq 1$.

[GS08, Definition 4.1] took the approach of axiomatising these properties along with something called dimension. In that vein we define the **doubling dimension** of a Bohr system B to be

$$\dim^* B = \sup \left\{ \log_2 \mathcal{C} \left(B_\eta; B_{\frac{1}{2}\eta} \right) : \eta \in (0, 1] \right\}.$$

It may be instructive to consider two examples.

Lemma 3.2 (Bohr systems of very low doubling dimension).

- (i) *Suppose that B is a Bohr system with $\dim^* B < 1$. Then there is a subgroup $H \leq G$ such that $B_\eta = H$ for all $\eta \in (0, 1]$.*
- (ii) *Conversely, suppose that $H \leq G$. Then the constant vector B with $B_\eta = H$ for all $\eta \in (0, 1]$ is a Bohr system and $\dim^* B = 0$.*

¹We call these *generalised* Bohr sets because usually (e.g. [TV06, Definition 4.6]) Bohr sets are defined using only the constant functions; we use this more general definition to ensure that the intersection of two Bohr sets is a Bohr set, but quite apart from being a natural extension this is by no means the first time this has been done (see e.g. [Bou08, (0.11)] and [Ruz09, Definition 5.1]).

Proof. First, since $\dim^* B < 1$ we see that for each $\eta \in (0, 1]$ there is a set X_η with $|X_\eta| < 2^1 = 2$ such that $B_\eta \subset X_\eta + B_{\frac{1}{2}\eta}$. Since B_η is non-empty we see that $0 < |X_\eta| < 2$ and so $|X_\eta| = 1$. Write $X_1 = \{x_1\}$. Then

$$B_1 - B_1 \subset \left(x_1 + B_{\frac{1}{2}}\right) - \left(x_1 + B_{\frac{1}{2}}\right) = B_{\frac{1}{2}} - B_{\frac{1}{2}} \subset B_1,$$

and so for all $x, y \in B_1$ we have $x - y \in B_1$ and so there is some subgroup $H \leq G$ such that $B_1 = H$. We show by induction that for each $i \in \mathbb{N}_0$ the set $B_{2^{-i}}$ contains a translate of H , from which the result follows since $0_G \in B_{2^{-i}}$.

Turning to the induction: the base case of $i = 0$ holds trivially. Suppose that $B_{2^{-i}}$ contains a translate of H . Then there is some set $X_{2^{-i}} = \{x_{2^{-i}}\}$ such that $B_{2^{-i}} \subset x_{2^{-i}} + B_{2^{-(i+1)}}$, whence $B_{2^{-(i+1)}}$ contains a translate of H as required and the first result is proved.

In the other direction, simply let $\Gamma := \{\gamma : \gamma(x) = 1 \text{ for all } x \in G\}$ and let δ be the constant function $1/|G|$. Writing B for the Bohr system generated by Γ and δ we see that $H \subset B_\eta$ for all $\eta \in (0, 1]$. On the other hand if $x \in B_1$ then $|G|\|\gamma(x)\| < 1$ and

$$\begin{aligned} \cos(2\pi|G|\|\gamma(x)\|) &= \frac{1}{2} (\exp(2\pi i|G|\|\gamma(x)\|) + \exp(-2\pi i|G|\|\gamma(x)\|)) \\ &= \frac{1}{2} \left(\gamma(x)^{|G|} + \overline{\gamma(x)^{|G|}} \right) = 1. \end{aligned}$$

It follows that $2\pi|G|\|\gamma(x)\| \in 2\pi\mathbb{Z}$ and hence $|G|\|\gamma(x)\| \in \mathbb{Z}$. We conclude that $\|\gamma(x)\| = 0$ and hence $\gamma(x) = 1$ for all $x \in G$ and $\gamma \in \Gamma$. It follows that $B_1 = H$ and hence B is a constant vector by nesting. It remains to note that $\mathcal{C}(H; H) = 1$ and so $\dim^* B = \log_2 1 = 0$ as claimed. \square

We say that a Bohr system B has **rank** k if it can be generated by a pair (Γ, δ) with $|\Gamma| = k$.

Lemma 3.3 (Rank 1 Bohr systems). *Suppose that B is a rank 1 Bohr system. Then $\dim^* B \leq \log_2 3$.*

Proof. Let (Γ, δ) generate B where $\Gamma = \{\gamma\}$ and write $\delta = \delta(\gamma)$. Suppose that $\eta \in (0, 1]$. We shall show that there is some $x \in G$ such that

$$(3.1) \quad B_\eta \subset \{-x, 0, x\} + B_{\frac{1}{2}\eta}.$$

If $B_\eta = B_{\frac{1}{2}\eta}$ then we may take $x = 0_G$ and be done; if not let $x \in B_\eta \setminus B_{\frac{1}{2}\eta}$ be such that $\|\gamma(x)\|$ is minimal. Let $\psi \in (-\frac{1}{2}, \frac{1}{2}]$ be such that $\gamma(x) = \exp(2\pi i\psi)$; note that $\|\gamma(x)\| = |\psi|$.

Suppose that $y \in B_\eta \setminus B_{\frac{1}{2}\eta}$ and let $\theta \in (-\frac{1}{2}, \frac{1}{2}]$ be such that $\gamma(y) = \exp(2\pi i\theta)$; note that $\|\gamma(y)\| = |\theta|$. Since $x \notin B_{\frac{1}{2}\eta}$, $|\psi|$ is minimal, and $y \in B_\eta$ we have

$$\frac{1}{2}\eta\delta \leq \|\gamma(x)\| = |\psi| \leq |\theta| = \|\gamma(y)\| < \eta\delta.$$

Thus if ψ and θ have the same sign then

$$|\theta - \psi| = ||\theta| - |\psi|| = |\theta| - |\psi| < \eta\delta - \frac{1}{2}\eta\delta = \frac{1}{2}\eta\delta,$$

and hence $\|\gamma(y-x)\| < \frac{1}{2}\eta\delta$ (since $\gamma(y-x) = \exp(2\pi i(\theta-\psi))$), so $y \in x + B_{\frac{1}{2}\eta}$. Similarly if ψ and θ have opposite signs then $|\theta+\psi| < \frac{1}{2}\eta\delta$ and $\|\gamma(y+x)\| < \frac{1}{2}\eta\delta$, and so $y \in -x + B_{\frac{1}{2}\eta}$. The claimed inclusion (3.1) follows and the result is proved. \square

We define the **width** of a Bohr system B to be

$$w(B) := \inf \{ \|\delta\|_{\ell_\infty(\Gamma)} : (\Gamma, \delta) \text{ generates } B \}.$$

Lemma 3.4. *Suppose that B is a Bohr system and $w(B) < \frac{1}{4}$. Then*

$$\dim^* B \leq \log_2 \mathcal{C} \left(B_1; B_{\frac{1}{8}} \right) \leq 3 \dim^* B$$

To prove this we shall use the following trivial observation.

Observation. *Suppose that γ is a character, $x \in G$, and $n \in \mathbb{N}$. Then*

$$\|\gamma(nx)\| = n\|\gamma(x)\| \text{ provided } \|\gamma(x)\| < \frac{1}{2n}.$$

Proof. Let θ, ψ be such that $\|\gamma(x)\| = |\theta|$, $\|\gamma(nx)\| = |\psi|$, $\gamma(x) = \exp(2\pi i\theta)$, and $\gamma(nx) = \exp(2\pi i\psi)$. Since γ is a homomorphism, $\gamma(nx) = \gamma(x)^n = \exp(2\pi i\theta n)$, and so $n\theta - \psi \in \mathbb{Z}$. However, $|n\theta - \psi| < n|\theta| + |\psi| < 1$ (since $|\theta| < \frac{1}{2n}$ and $|\psi| \leq \frac{1}{2}$) and so $\psi = n\theta$ and the result is proved. \square

Proof of Lemma 3.4. The right hand inequality is easy from Lemma 2.1 part (iii) and the definition of doubling dimension:

$$\log_2 \mathcal{C} \left(B_1; B_{\frac{1}{8}} \right) \leq \log_2 \mathcal{C} \left(B_1; B_{\frac{1}{2}} \right) + \log_2 \mathcal{C} \left(B_{\frac{1}{2}}; B_{\frac{1}{4}} \right) + \log_2 \mathcal{C} \left(B_{\frac{1}{4}}; B_{\frac{1}{8}} \right) \leq 3 \dim^* B.$$

In the other direction, since $w(B) < \frac{1}{4}$ there is a pair (Γ, δ) generating B such that $\|\delta\|_{\ell_\infty(\Gamma)} < \frac{1}{4}$.

Suppose that $\eta \in (0, 1]$ and let $X \subset B_\eta$ be $B_{\frac{1}{2}\eta}$ -separated i.e. if $x, y \in X$ have $x-y \in B_{\frac{1}{2}\eta}$ then $x = y$. Let $k \in \mathbb{N}$ be a natural number such that $\frac{1}{2} \leq \eta k \leq 1$ (the reason for which choice will become clear). Then by nesting of Bohr sets and Lemma 2.1 part (i) we have

$$\mathcal{C} \left(B_{\eta k}; B_{\frac{1}{4}\eta k} \right) \leq \mathcal{C} \left(B_1; B_{\frac{1}{8}} \right)$$

and so there is a set Z such that $B_{\eta k} \subset Z + B_{\frac{1}{4}\eta k}$ and $|Z| \leq \mathcal{C} \left(B_1; B_{\frac{1}{8}} \right)$.

Since $\eta k \leq 1$ and each $x \in X$ has $x \in B_\eta$ we conclude (by sub-additivity) that $kx \in B_{\eta k}$, and hence there is some $z(x) \in Z$ such that $kx \in z(x) + B_{\frac{1}{4}\eta k}$. Suppose that $z(x) = z(y)$ for $x, y \in X$. By sub-additivity and nesting we have

$$x - y \in B_{2\eta} \subset B_{\frac{2}{k}} \text{ and } k(x - y) \in B_{\frac{1}{4}\eta k} - B_{\frac{1}{4}\eta k} \subset B_{\frac{1}{2}\eta k}.$$

Suppose that $\gamma \in \Gamma$. Then we have just seen that $\|\gamma(x-y)\| < \frac{2}{k}\delta(\gamma) < \frac{1}{2k}$ (since $\delta(\gamma) < \frac{1}{4}$) and so by the Observation we see that

$$k\|\gamma(x-y)\| = \|\gamma(k(x-y))\| < \frac{1}{2}\eta k\delta(\gamma).$$

Dividing by k and noting that γ was an arbitrary element of Γ it follows that $x - y \in B_{\frac{1}{2}\eta}$ and hence $x = y$. We conclude that the function z is injective and hence $|X| \leq |Z| \leq \mathcal{C}(B_1; B_{\frac{1}{8}})$.

Finally, if X is maximal with the given property then for any $y \in B_\eta$ either $y \in X$ and so $y \in X + B_{\frac{1}{2}\eta}$ or else there is some $x \in X$ such that $y \in x + B_{\frac{1}{2}\eta}$. It follows that

$$B_\eta \subset X + B_{\frac{1}{2}\eta},$$

and the left hand inequality is proved given the upper bound on $|X|$. \square

We can make new Bohr systems from old by taking intersections: given Bohr systems B and B' we define their **intersection** to be

$$B \wedge B' := (B_\eta \cap B'_\eta)_{\eta \in (0,1]}.$$

Writing $\mathcal{B}(G)$ for the set of Bohr systems on G we then have a lattice structure as captured by the following trivial lemma.

Lemma 3.5 (Lattice structure). *The pair $(\mathcal{B}(G), \wedge)$ is a meet-semilattice, meaning that it satisfies*

- (i) (Closure) $B \wedge B' \in \mathcal{B}(G)$ for all $B, B' \in \mathcal{B}(G)$;
- (ii) (Associativity) $(B \wedge B') \wedge B'' = B \wedge (B' \wedge B'')$ for all $B, B', B'' \in \mathcal{B}(G)$;
- (iii) (Commutativity) $B \wedge B' = B' \wedge B$ for all $B, B' \in \mathcal{B}(G)$;
- (iv) (Idempotence) $B \wedge B = B$ for all $B \in \mathcal{B}(G)$.

Proof. The only property with any content is the first, the truth of which is dependent on the slightly more general definition of Bohr set we made. Suppose that B is generated by (Γ, δ) and B' is generated by (Γ', δ') . Then consider the Bohr system B'' generated by $(\Gamma \cup \Gamma', \delta \wedge \delta')$ where

$$\delta \wedge \delta' : \Gamma \cup \Gamma' \rightarrow \mathbb{R}_{>0}; \gamma \mapsto \begin{cases} \delta(\gamma) & \text{if } \gamma \in \Gamma \setminus \Gamma' \\ \delta'(\gamma) & \text{if } \gamma \in \Gamma' \setminus \Gamma \\ \min\{\delta(\gamma), \delta'(\gamma)\} & \text{if } \gamma \in \Gamma \cap \Gamma' \end{cases}.$$

It is easy to check that $B'' = B \wedge B'$ and hence $B \wedge B' \in \mathcal{B}(G)$. The remaining properties are inherited from the meet-semilattice $(\mathcal{P}(G), \cap)^{(0,1]}$. \square

As usual this structure gives rise to a partial order on $\mathcal{B}(G)$ where we write $B' \leq B$ if $B' \wedge B = B'$.

Another way we can produce new Bohr systems is via dilation: given a Bohr system B and a parameter $\lambda \in (0, 1]$, we write λB for the λ -**dilate** of B , and define it to be the vector

$$\lambda B = (B_{\eta\lambda})_{\eta \in (0,1]}.$$

We then have the following trivial properties.

Lemma 3.6 (Basic properties of dilation).

(i) (Order-preserving action) *The map*

$$(0, 1] \times \mathcal{B}(G) \rightarrow \mathcal{B}(G); (\lambda, B) \mapsto \lambda B$$

is a well-defined order-preserving action of the monoid $((0, 1], \times)$ on the set of Bohr systems.

(ii) (Distribution over meet) *We have*

$$\lambda(B \wedge B') = (\lambda B) \wedge (\lambda B') \text{ for all } B, B' \in \mathcal{B}(G), \lambda \in (0, 1].$$

The doubling dimension interacts fairly well with intersection and dilation and it can be shown that

$$\dim^* \lambda B \leq \dim^* B \text{ and } \dim^* B \wedge B' = O(\dim^* B + \dim^* B')$$

for Bohr systems B, B' and $\lambda \in (0, 1]$. (The first of these is trivial; the second requires a little more work.)

The big- O here is inconvenient in applications and to deal with this we define a variant which is equivalent, but which behaves a little better under intersection. The **dimension** of a Bohr system B is defined to be

$$\dim B = \sup \left\{ \log_2 \mathcal{C}^\Delta \left(B_\eta; B_{\frac{1}{2}\eta} \right) : \eta \in (0, 1] \right\}.$$

Lemma 3.7 (Basic properties of dimension).

(i) (Sub-additivity of dimension w.r.t. intersection) *For all $B, B' \in \mathcal{B}(G)$ we have*

$$\dim B \wedge B' \leq \dim B + \dim B'.$$

(ii) (Monotonicity of dimension w.r.t. dilation) *For all $B \in \mathcal{B}(G)$ and $\lambda \in (0, 1]$ we have*

$$\dim \lambda B \leq \dim B.$$

(iii) (Equivalence of dimension and doubling dimension) *For all $B \in \mathcal{B}(G)$ we have*

$$\dim^* B \leq \dim B \leq 2 \dim^* B.$$

Proof. First, from Lemma 2.4, part (ii) we have

$$\begin{aligned} \mathcal{C}^\Delta \left((B \wedge B')_\eta; (B \wedge B')_{\frac{1}{2}\eta} \right) &= \mathcal{C}^\Delta \left(B_\eta \cap B'_\eta; B_{\frac{1}{2}\eta} \cap B'_{\frac{1}{2}\eta} \right) \\ &\leq \mathcal{C}^\Delta \left(B_\eta; B_{\frac{1}{2}\eta} \right) \mathcal{C}^\Delta \left(B'_\eta; B'_{\frac{1}{2}\eta} \right) \end{aligned}$$

for all $\eta \in (0, 1]$. Taking logs the sub-additivity of dimension follows since suprema are sub-linear.

Secondly, monotonicity follows immediately since

$$\begin{aligned} \dim \lambda B &= \sup \left\{ \log_2 \mathcal{C}^\Delta \left((\lambda B)_\eta; (\lambda B)_{\frac{1}{2}\eta} \right) : \eta \in (0, 1] \right\} \\ &= \sup \left\{ \log_2 \mathcal{C}^\Delta \left(B_\eta; B_{\frac{1}{2}\eta} \right) : \eta \in (0, \lambda] \right\} \leq \dim B. \end{aligned}$$

Finally, it follows from Lemma 2.4 part (iv) that $\dim^* B \leq \dim B$. On the other hand from the sub-additivity and symmetry of Bohr sets we have $B_{\frac{1}{2}\eta} \supset B_{\frac{1}{4}\eta} - B_{\frac{1}{4}\eta}$, and so by Lemma 2.4 parts (i) and (iii) we get

$$\mathcal{C}^\Delta \left(B_\eta; B_{\frac{1}{2}\eta} \right) \leq \mathcal{C}^\Delta \left(B_\eta; B_{\frac{1}{4}\eta} - B_{\frac{1}{4}\eta} \right) \leq \mathcal{C} \left(B_\eta; B_{\frac{1}{4}\eta} \right).$$

Hence by Lemma 2.1 part (iii) and the definition of doubling dimension we have

$$\mathcal{C} \left(B_\eta; B_{\frac{1}{4}\eta} \right) \leq \mathcal{C} \left(B_\eta; B_{\frac{1}{2}\eta} \right) \mathcal{C} \left(B_{\frac{1}{2}\eta}; B_{\frac{1}{4}\eta} \right) \leq 2^{2 \dim^* B},$$

and so $\dim B \leq 2 \dim^* B$ as claimed. \square

As well as the various notion of dimension, Bohr systems also have a notion of size relative to some ‘reference’ set. Very roughly we think of the ‘size’ of a Bohr system B relative to some reference set A as being $\mathcal{C}^\Delta(A; B_1)$. This quantity is then governed by the following lemma.

Lemma 3.8 (Size of Bohr systems). *Suppose that B is a Bohr system and $A \subset G$. Then the following hold.*

(i) (Size of dilates) *For all $\lambda \in (0, 1]$ we have*

$$\mathcal{C}^\Delta(A; (\lambda B)_1) \leq \mathcal{C}^\Delta(A; B_1) (4\lambda^{-1})^{\dim B}.$$

(ii) (Size and non-triviality) *If $\mathcal{C}^\Delta(A; B_1) < |A|$ then there is some $x \in B_1$ with $x \neq 0_G$.*

Proof. By symmetry and sub-additivity of Bohr sets we see that $(\lambda B)_1 \supset B_{\frac{1}{2}\lambda} - B_{\frac{1}{2}\lambda}$ and so by Lemma 2.4 parts (i) and (iii) we have

$$\mathcal{C}^\Delta(A; (\lambda B)_1) \leq \mathcal{C}^\Delta \left(A; B_{\frac{1}{2}\lambda} - B_{\frac{1}{2}\lambda} \right) \leq \mathcal{C} \left(A; B_{\frac{1}{2}\lambda} \right).$$

Write r for the largest natural number such that $2^r \lambda \leq 1$. By Lemma 2.1 part (iii) we see that

$$\begin{aligned} \mathcal{C} \left(A; B_{\frac{1}{2}\lambda} \right) &\leq \mathcal{C} \left(A; B_{2^r \lambda} \right) \prod_{i=0}^r \mathcal{C} \left(B_{2^i \lambda}; B_{2^{i-1} \lambda} \right) \\ &\leq \mathcal{C} \left(A; B_1 \right) \mathcal{C} \left(B_1; B_{2^r \lambda} \right) \prod_{i=0}^r \mathcal{C} \left(B_{2^i \lambda}; B_{2^{i-1} \lambda} \right) \\ &\leq \mathcal{C} \left(A; B_1 \right) 2^{(r+2) \dim^* B} \leq \mathcal{C}^\Delta \left(A; B_1 \right) 2^{(r+2) \dim B}, \end{aligned}$$

where the last inequality is by Lemma 2.4 part (iv) and the first inequality in Lemma 3.7 part (iii). The first part follows.

By Lemma 2.4 part (iv) we then see that $\mathcal{C}(A; B_1) \leq \mathcal{C}^\Delta(A; B_1) < |A|$. It follows that there is some set X with $|X| < |A|$ such that $A \subset X + B_1$ whence $|A| \leq |X||B_1| < |A||B_1|$ which implies that $|B_1| > 1$ and hence contains a non-trivial element establishing the second part. \square

4. MEASURES, CONVOLUTION AND APPROXIMATE INVARIANCE

Given a probability measure μ and a set S with $\mu(S) > 0$, we write μ_S for the probability measure induced by

$$C(X) \rightarrow \mathbb{C}; f \mapsto \frac{1}{\mu(S)} \int f 1_S d\mu.$$

Moreover, if S is a non-empty subset of G then we write m_S for $(m_G)_S$. (Note that this notation is consistent since $m_G = (m_G)_G$.)

Given $f \in C(G)$ and an element $x \in G$ we define

$$\tau_x(f)(y) := f(y - x) \text{ for all } y \in G.$$

We write $M(G)$ for the space of complex-valued measures on G and recall that each $\mu \in M(G)$ naturally defines a linear functional

$$C(G) \rightarrow \mathbb{C}; f \mapsto \langle f, \mu \rangle := \int f(x) d\mu(x).$$

Moreover, these are all the linear functionals. (This is the Riesz Representation Theorem [Rud90, E4], though of course it is rather simple in our setting of finite G .)

Given $\mu \in M(G)$ we define $\tau_x(\mu)$ to be the measure induced by

$$C(G) \rightarrow \mathbb{C}; f \mapsto \int \tau_{-x}(f) d\mu.$$

We also write $\tilde{\mu}$ for the measure induced by

$$C(G) \rightarrow \mathbb{C}; f \mapsto \int \overline{f(-x)} d\mu(x),$$

and given a further measure $\nu \in M(G)$ we define the **convolution** of μ and ν to be the measure

$$\mu * \nu := \int \tau_x(\tilde{\nu}) d\mu(x).$$

This operation makes $M(G)$ into a commutative Banach algebra with unit; for details see [Rud90, §1.3.1].

This notation all extends in the expected way to functions so that if $f \in L_1(m_G)$ then \tilde{f} is defined point-wise by

$$\tilde{f}(x) := \overline{f(-x)} \text{ for all } x \in G,$$

and given a further $g \in L_1(m_G)$ we define the **convolution** of f and g to be $f * g$ which is determined point-wise by

$$f * g(x) = \int f(y) g(x - y) dm_G(y) \text{ for all } x \in G.$$

This can be written slightly differently using the inner product on $L_2(m_G)$. If $g, f \in L_2(m_G)$ then

$$\langle f, g \rangle_{L_2(m_G)} = \int f(x) \overline{g(x)} dm_G(x),$$

and

$$f * g(x) = \langle f, \tau_x(\tilde{g}) \rangle_{L_2(m_G)} \text{ for all } x \in G.$$

Finally, if $f \in L_1(m_G)$ and $\mu \in M(G)$ then

$$\mu * f(x) = f * \mu(x) = \int f(y) d\mu(x - y).$$

Given a Bohr system B we say that a probability measure μ on G is **B -approximately invariant** if for every $\eta \in (0, 1]$ there are probability measures μ_η^+ and μ_η^- such that

$$(1 - \eta)\mu_\eta^- \leq \tau_x(\mu) \leq (1 + \eta)\mu_\eta^+ \text{ for all } x \in B_\eta.$$

It may be worth remembering at that for two measures ν and κ we say $\nu \geq \kappa$ if and only if $\nu - \kappa$ is non-negative.

To motivate the name in this definition we have the following lemma.

Lemma 4.1. *Suppose that B is a Bohr system and μ is B -approximately invariant. Then for all $\eta \in (0, 1]$ we have*

$$\|\mu - \tau_x(\mu)\| \leq \eta \text{ for all } x \in B_{\frac{1}{2}\eta}.$$

Proof. Suppose that $x \in B_{\frac{1}{2}\eta}$. Then

$$\left(1 - \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^- \leq \tau_x(\mu) \leq \left(1 + \frac{\eta}{2}\right) \mu_{\frac{1}{2}\eta}^+ \text{ and } \left(1 - \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^- \leq \mu \leq \left(1 + \frac{\eta}{2}\right) \mu_{\frac{1}{2}\eta}^+.$$

It follows that

$$\tau_x(\mu) - \mu \leq \left(1 + \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^+ - \left(1 - \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^-,$$

and

$$\tau_x(\mu) - \mu \geq \left(1 - \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^- - \left(1 + \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^+.$$

The Jordan decomposition theorem tells us that there are two measurable sets P and N (which together form a partition of G) such that $\tau_x(\mu) - \mu$ is a non-negative measure on P and a non-positive measure on N . We conclude that

$$\begin{aligned} \|\tau_x(\mu) - \mu\| &= (\tau_x(\mu) - \mu)(P) - (\tau_x(\mu) - \mu)(N) \\ &\leq \left(1 + \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^+(P) - \left(1 - \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^-(P) \\ &\quad + \left(1 + \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^+(N) - \left(1 - \frac{1}{2}\eta\right) \mu_{\frac{1}{2}\eta}^-(N) \\ &= \left(1 + \frac{1}{2}\eta\right) - \left(1 - \frac{1}{2}\eta\right) = \eta, \end{aligned}$$

since μ_η^+ and μ_η^- are probability measures and $N \sqcup P = G$. The result is proved. \square

This can be slightly generalised in the following convenient way.

Lemma 4.2. *Suppose that B is a Bohr system and μ is a B -approximately invariant probability measure. Then*

$$\|\tau_x(f * \mu) - f * \mu\|_{L_\infty(G)} \leq \eta \|f\|_{L_\infty(G)} \text{ for all } x \in B_{\frac{1}{2}\eta}.$$

Proof. Simply note that

$$|f * \mu(y - x) - f * \mu(y)| \leq \int |f(z)| d|\tau_x(\mu) - \mu|(z) \leq \eta \|f\|_{L_\infty(G)}$$

by the triangle inequality and Lemma 4.1. \square

Approximately invariant probability measures are closed under convolution with probability measures.

Lemma 4.3. *Suppose that B is a Bohr system, μ is a B -approximately invariant probability measure, and ν is a probability measure. Then $\mu * \nu$ is a B -approximately invariant probability measure.*

Proof. Since μ is B -approximately invariant there are probability measures $(\mu_\eta^-)_{\eta \in (0,1]}$ and $(\mu_\eta^+)_{\eta \in (0,1]}$ such that

$$(1 - \eta)\mu_\eta^- \leq \tau_x(\mu) \leq (1 + \eta)\mu_\eta^+ \text{ for all } x \in B_\eta.$$

Since ν is a probability measure we can integrate the above inequalities to get

$$(1 - \eta)\mu_\eta^- * \nu \leq \tau_x(\mu) * \nu \leq (1 + \eta)\mu_\eta^+ * \nu \text{ for all } x \in B_\eta.$$

But then since $\tau_x(\mu) * \nu = \tau_x(\mu * \nu)$ we can put $(\mu * \nu)_\eta^- := \mu_\eta^- * \nu$ and $(\mu * \nu)_\eta^+ := \mu_\eta^+ * \nu$ to get the required family of measures for $\mu * \nu$. \square

The last result of this section is essentially [Bou99, Lemma 3.0] and ensures a plentiful supply of approximately invariant probability measures.

Proposition 4.4. *Suppose that B is a Bohr system, and X is a non-empty set with $m_G(X + B_1) \leq Km_G(X)$. Then there is a λB -approximately invariant probability measure with support contained in $X + B_1$ for some $1 \geq \lambda \geq \frac{1}{24 \log 2K}$.*

Proof. Let $C := 24$ and $\lambda := 1/C \log 2K$. Note that $K \geq 1$ and so $\lambda < 1/6$. Suppose that for all $\kappa \in [\frac{1}{4}, \frac{3}{4}]$ there is some $\delta_\kappa \in (0, \lambda]$ such that

$$\frac{m_G(X + B_{\kappa + \delta_\kappa})}{m_G(X + B_{\kappa - \delta_\kappa})} > \exp\left(\frac{1}{2}\lambda^{-1}\delta_\kappa\right).$$

Write $I_\kappa := [\kappa - \delta_\kappa, \kappa + \delta_\kappa]$, and note that $\bigcup_\kappa I_\kappa \supset [\frac{1}{4}, \frac{3}{4}]$. By the Vitalli covering lemma we conclude that there is a sequence $\kappa_1 < \dots < \kappa_m$ such that the intervals $(I_{\kappa_i})_{i=1}^m$ are disjoint and

$$\sum_{i=1}^m 2\delta_{\kappa_i} = \sum_{i=1}^m \mu(I_{\delta_{\kappa_i}}) \geq \frac{1}{3} \mu\left(\left[\frac{1}{4}, \frac{3}{4}\right]\right) = \frac{1}{6}.$$

Since the intervals $(I_{\kappa_i})_{i=1}^m$ are disjoint, $(\kappa_i)_{i=1}^m$ is an increasing sequence, and $\delta_{\kappa_1}, \delta_{\kappa_m} \leq \lambda < \frac{1}{4}$ we see that

$$0 < \kappa_1 - \delta_{\kappa_1} < \kappa_1 + \delta_{\kappa_1} < \cdots < \kappa_i + \delta_{\kappa_i} < \kappa_{i+1} - \delta_{\kappa_{i+1}} < \cdots < \kappa_m + \delta_{\kappa_m} < 1,$$

and hence

$$\begin{aligned} \exp(1/24\lambda) &\leq \exp\left(\frac{1}{4}\lambda^{-1} \sum_{i=1}^m 2\delta_{\kappa_i}\right) = \prod_{i=1}^m \exp\left(\frac{1}{2}\lambda^{-1}\delta_{\kappa_i}\right) \\ &< \prod_{i=1}^m \frac{m_G(X + B_{\kappa_i + \delta_{\kappa_i}})}{m_G(X + B_{\kappa_i - \delta_{\kappa_i}})} \\ &= \frac{m_G(X + B_{\kappa_m + \delta_{\kappa_m}})}{m_G(X + B_{\kappa_1 - \delta_{\kappa_1}})} \cdot \prod_{i=1}^{m-1} \frac{m_G(X + B_{\kappa_i + \delta_{\kappa_i}})}{m_G(X + B_{\kappa_{i+1} - \delta_{\kappa_{i+1}}})} \\ &\leq \frac{m_G(X + B_1)}{m_G(X)} \leq K. \end{aligned}$$

This is a contradiction and so there is some $\kappa \in [\frac{1}{4}, \frac{3}{4}]$ such that

$$\frac{m_G(X + B_{\kappa + \delta_{\kappa}})}{m_G(X + B_{\kappa - \delta_{\kappa}})} \leq \exp\left(\frac{1}{2}\lambda^{-1}\delta\right) \text{ for all } \delta \in (0, \lambda].$$

Let μ be the uniform probability measure on $X + B_{\kappa}$, and for each $\eta \in (0, 1]$ let μ_{η}^{-} be the uniform probability measure on $X + B_{\kappa - \lambda\eta}$ and μ_{η}^{+} be the uniform probability measure on $X + B_{\kappa + \lambda\eta}$. If $x \in (\lambda B)_{\eta}$ then $x \in B_{\lambda\eta}$ and so

$$\tau_x(\mu) \leq \frac{m_G(X + B_{\kappa + \lambda\eta})}{m_G(X + B_{\kappa})} \mu_{\eta}^{+} \leq \exp\left(\frac{1}{2}\lambda^{-1}\lambda\eta\right) \mu_{\eta}^{+} \leq (1 + \eta)\mu_{\eta}^{+},$$

since $1 + x \geq \exp(x/2)$ whenever $0 \leq x \leq 1$. Similarly

$$\tau_x(\mu) \geq \frac{m_G(X + B_{\kappa - \lambda\eta})}{m_G(X + B_{\kappa})} \mu_{\eta}^{-} \geq \exp\left(-\frac{1}{2}\lambda^{-1}\lambda\eta\right) \mu_{\eta}^{-} \geq (1 - \eta)\mu_{\eta}^{-},$$

since $1 - x \leq \exp(-x/2)$ whenever $0 \leq x \leq 1$. The result is proved. \square

For applications it will often be useful to have the following corollary.

Corollary 4.5. *Suppose that B is a Bohr system with $\dim B \leq d$ for some parameter $d \geq 1$. Then there is some $\lambda \in (\Omega(d^{-1}), 1]$ and a λB -approximately invariant probability measure μ supported on B_1 .*

Proof. Put $X := B_{\frac{1}{2}}$ and $B' := \frac{1}{2}B$. By Lemma 2.2 we know that

$$m_G(X + B'_1) = m_G(B_{\frac{1}{2}} + B_{\frac{1}{2}}) \leq \mathcal{C}\left(B_{\frac{1}{2}}; B_{\frac{1}{4}}\right)^2 m_G(B_{\frac{1}{4}} + B_{\frac{1}{4}}).$$

However, by sub-additivity of Bohr sets $B_{\frac{1}{4}} + B_{\frac{1}{4}} \subset B_{\frac{1}{2}} = X$. Thus given the definition of doubling dimension and the first inequality in Lemma 3.7 part (iii) we see that

$$\frac{m_G(X + B'_1)}{m_G(X)} \leq \mathcal{C} \left(B_{\frac{1}{2}}; B_{\frac{1}{4}} \right)^2 \leq 2^{2 \dim^* B} \leq 2^{2d}.$$

By Proposition 4.4 applied to X and B' there is a $\lambda B'$ -approximately invariant probability measure μ with support in $X + B'_1 = B_{\frac{1}{2}} + B_{\frac{1}{2}} \subset B_1$. The result follows since $\lambda \geq 1/24 \log 2^{2d+1}$ and $\lambda B' = \frac{\lambda}{2} B$. \square

5. APPROXIMATE ANNIHILATORS

We shall understand the dual group of G through what we call ‘approximate annihilators’, though this nomenclature is non-standard.

Given a set $S \subset G$ and a parameter $\rho > 0$ we define the **ρ -approximate annihilator** of S to be the set

$$N(S, \rho) := \{\gamma \in \widehat{G} : |1 - \gamma(x)| < \rho \text{ for all } x \in S\}.$$

Approximate annihilators enjoy many of the same properties as Bohr sets as we record in the following trivial lemma (an analogue of Lemma 3.1).

Lemma 5.1 (Properties of approximate annihilators). *Suppose that S is a set. Then*

- (i) (Identity) $0_{\widehat{G}} \in N(S, \rho)$ for all $\rho > 0$;
- (ii) (Symmetry) $N(S, \rho) = -N(S, \rho)$ for all $\rho > 0$;
- (iii) (Nesting) $N(S, \rho) \subset N(S, \rho')$ whenever $0 < \rho \leq \rho'$;
- (iv) (Sub-additivity) $N(S, \rho) + N(S, \rho') \subset N(S, \rho + \rho')$ for all $\rho, \rho' > 0$.

Approximate annihilators and approximately invariant measures interact rather well as is captured by the following version of [GK09, Lemma 3.6].

Lemma 5.2 (Majorising annihilators). *Suppose that B is a Bohr system with μ a B -approximately invariant probability measure, and $\kappa, \eta \in (0, 1]$ are parameters. Then*

$$\{\gamma \in \widehat{G} : |\widehat{\mu}(\gamma)| > \kappa\} \subset N(B_{\frac{1}{2}\kappa\eta}, \eta).$$

Proof. Suppose that $|\widehat{\mu}(\gamma)| \geq \kappa$ and $y \in B_{\frac{1}{2}\kappa\eta}$. Then $-y \in B_{\frac{1}{2}\kappa\eta}$ by symmetry and so by Lemma 4.1 we have

$$|1 - \gamma(y)|\kappa < \left| \int \gamma(x) d\mu(x) - \int \gamma(x + y) d\mu(x) \right| \leq \|\mu - \tau_{-y}(\mu)\| \leq \eta\kappa.$$

The result follows on dividing by κ . \square

In the more general topological setting where G is not assumed finite, approximate annihilators form a base for the topology of the dual group [Rud90, Theorem 1.2.6]. [Rud90, Theorem 1.2.6] also captures the natural duality between our approximate annihilators and sets of the form

$$(5.1) \quad \{x \in G : |1 - \gamma(x)| < \rho \text{ for all } x \in \Gamma\} \text{ for } \Gamma \subset \widehat{G}.$$

A number of elements of this paper would be neater if our Bohr sets were replaced by (a suitable generalisation of) sets of the form given in (5.1). The only benefit we know of arising from our choice is that the proof of Lemma 3.4 is slightly easier for vectors of Bohr sets.

For us the duality in [Rud90, Theorem 1.2.6] is captured in the following lemma.

Lemma 5.3 (Duality of Bohr sets and approximate annihilators).

(i) *If X is a non-empty subset of G and $\epsilon \in (0, 1]$ then*

$$X \subset \text{Bohr}(N(X, \epsilon), \delta) \text{ where } \delta := \frac{\epsilon}{2\sqrt{2}} \cdot 1_{N(X, \epsilon)};$$

(ii) *if Γ is a non-empty set of characters of G and $\delta : \Gamma \rightarrow \mathbb{R}_{>0}$ then*

$$\Gamma \subset N(\text{Bohr}(\Gamma, \delta), \epsilon) \text{ where } \epsilon = 2\pi\|\delta\|_{\ell_\infty(\Gamma)}.$$

Proof. First note that

$$1 - \frac{\theta^2}{2} \leq \cos \theta \leq 1 - \frac{2\theta^2}{\pi^2} \text{ whenever } |\theta| \leq \pi.$$

On the other hand $\|z\| \leq \frac{1}{2}$ for all $z \in S^1$ and

$$\sqrt{2 - 2\cos 2\pi\|z\|} = |z - 1|.$$

It follows that

$$2\sqrt{2}\|\gamma(x)\| \leq |\gamma(x) - 1| \leq 2\pi\|\gamma(x)\| \text{ for all } x \in G, \gamma \in \widehat{G}.$$

The result is proved once we disentangle the meaning of the two claims. \square

The following is [TV06, Proposition 4.39] extended to two sets. The proof is the same.

Lemma 5.4. *Suppose that S, T are non-empty sets such that $m_G(S + T) \leq Km_G(S)$ and $\epsilon \in (0, 1]$ is a parameter. Then*

$$\{\gamma \in \widehat{G} : |\widehat{1_{S+T}}(\gamma)| > (1 - \epsilon)m_G(S + T)\} \subset N(T - T, 2\sqrt{2\epsilon K}).$$

Proof. For each $\gamma \in \widehat{G}$ let $\omega_\gamma \in S^1$ be such that $\overline{\omega_\gamma}\widehat{1_S}(\gamma) = |\widehat{1_S}(\gamma)|$. For all $t, t' \in T$ we then have

$$\begin{aligned} |\gamma(t) - \gamma(t')|^2 m_G(S) &\leq \int_S |\gamma(t + s) - \gamma(t' + s)|^2 dm_G(s) \\ &\leq 2 \left(\int_S |\gamma(t + s) - \omega_\gamma|^2 dm_G(s) \right. \\ &\quad \left. + \int_S |\gamma(t' + s) - \omega_\gamma|^2 dm_G(s) \right) \\ &\leq 4 \int_{S+T} |\gamma(x) - \omega_\gamma|^2 dm_G(x) = 8(m_G(S + T) - |\widehat{1_{S+T}}(\gamma)|). \end{aligned}$$

It follows that if $|\widehat{1_{S+T}}(\gamma)| > (1 - \epsilon)m_G(S + T)$ then

$$|\gamma(t - t') - 1| = |\gamma(t) - \gamma(t')| < 2\sqrt{2\epsilon K},$$

and the result is proved. \square

6. FOURIER ANALYSIS

In this section we turn our attention to the Fourier transform itself. First we have the Fourier inversion formula [Rud90, Theorem 1.5.1]: if $f \in A(G)$ then

$$f(x) = \sum_{\gamma \in \hat{G}} \hat{f}(\gamma) \gamma(x) \text{ for all } x \in G.$$

Since G is finite this is a purely algebraic statement which can be easily checked. It can be used to prove Parseval's theorem [Rud90, Theorem 1.6.2] that if $f, g \in L_2(m_G)$ then

$$(6.1) \quad \langle f, g \rangle_{L_2(m_G)} = \langle \hat{f}, \hat{g} \rangle_{\ell_2(\hat{G})} = \sum_{\gamma \in \hat{G}} \hat{f}(\gamma) \overline{\hat{g}(\gamma)}.$$

One of the key uses of Bohr sets is as approximate invariant sets for functions.

Lemma 6.1. *Suppose that Γ is a set of k characters. Then there is a Bohr system B with $\mathcal{C}^\Delta(G; B_1) \leq 1$ and $\dim B = O(k)$, such that for every $f \in A(G)$ with $\text{supp } \hat{f} \subset \Gamma$ we have*

$$\|\tau_x(f) - f\|_{L_\infty(G)} \leq \epsilon \|f\|_{A(G)} \text{ whenever } x \in B_{\frac{1}{\pi}\epsilon}.$$

Proof. For each $\gamma \in \Gamma$ let $B^{(\gamma)}$ be the Bohr system with frequency set $\{\gamma\}$ and width function the constant function $\frac{1}{2}$ and put $B := \bigwedge_{\gamma \in \Gamma} B^{(\gamma)}$. (Equivalently, let B be the Bohr system with frequency set Γ and width function the constant function $\frac{1}{2}$.)

Since $\|z\| \leq \frac{1}{2}$ for all $z \in S^1$ we see that $B_1 = G$. It follows from Lemma 2.4 part (iii) that $\mathcal{C}^\Delta(G; B_1) = \mathcal{C}^\Delta(G; G - G) \leq \mathcal{C}(G; G)$. On the other hand $G \subset \{0_G\} + G$ and so $\mathcal{C}(G; G) \leq 1$ as claimed.

By Lemma 3.3 (and the second inequality in Lemma 3.7 part (iii)) we have $\dim B^{(\gamma)} = O(1)$ and by Lemma 3.7 part (i) we conclude that $\dim B = O(k)$.

Now, suppose that f is of the given form, meaning $\text{supp } \hat{f} \subset \Gamma$ and $f \in A(G)$. Then by Fourier inversion we have

$$|\tau_x(f)(y) - f(y)| = \left| \sum_{\gamma \in \Gamma} \hat{f}(\gamma) (\gamma(x+y) - \gamma(y)) \right| \leq \|f\|_{A(G)} \sup\{|\gamma(x) - 1| : \gamma \in \Gamma\}.$$

On the other hand the second part of Lemma 5.3 tells us that this supremum is at most $2\pi\frac{1}{2}\epsilon$ and the result is proved. \square

The next result is a variant of [CLS11, Lemma 3.2] proved using their beautiful method.

Lemma 6.2. *Suppose that $A \subset G$, B is a Bohr system, μ is B -approximately invariant, $g \in A(G)$, and $p \in [2, \infty)$ and $\epsilon \in (0, 1]$ are parameters. Then there is a Bohr system $B' \leq B$ with*

$$\mathcal{C}^\Delta(A; B'_1) \leq (2\epsilon^{-1})^{O(p\epsilon^{-2})} \mathcal{C}^\Delta(A; B_1) \text{ and } \dim B' \leq \dim B + O(p\epsilon^{-2})$$

such that

$$\|\tau_x(g) - g\|_{L_p(\mu)} \leq \epsilon \|g\|_{A(G)} \text{ for all } x \in B'_1.$$

Proof. We may certainly suppose that $g \not\equiv 0$ so that $\|g\|_{A(G)} > 0$ (or else simply take $B' := B$ and we are trivially done). Consider independent identically distributed random variables X_1, \dots, X_l taking values in $L_\infty(G)$ with

$$\mathbb{P}\left(X_i = \frac{\widehat{g}(\gamma)}{|\widehat{g}(\gamma)|} \gamma\right) = \frac{1}{\|g\|_{A(G)}} |\widehat{g}(\gamma)| \text{ for all } \gamma \in \widehat{G} \text{ such that } |\widehat{g}(\gamma)| \neq 0.$$

Note that this is well-defined since $0 < \|g\|_{A(G)} < \infty$. Moreover, by the Fourier inversion formula, we have

$$\mathbb{E}X_i(x) = \sum_{\gamma \in \widehat{G}} \gamma(x) \frac{\widehat{g}(\gamma)}{|\widehat{g}(\gamma)|} \cdot \frac{|\widehat{g}(\gamma)|}{\|g\|_{A(G)}} = \frac{g(x)}{\|g\|_{A(G)}} \text{ for all } x \in G.$$

Regarding the variables $X_i(x) - g(x)$ as elements of $L_p(\mathbb{P}^l)$ and noting, further, that

$$\|X_i(x) - g(x)\|_{L_\infty(\mathbb{P}^l)} \leq \|X_i(x)\|_{L_\infty(\mathbb{P}^l)} + \|g(x)\|_{L_\infty(\mathbb{P}^l)} = 1 + \frac{|g(x)|}{\|g\|_{A(G)}} \leq 2,$$

we can apply the Marcinkiewicz-Zygmund inequality (see *e.g.* [CLS11, Lemma 3.1]) to get

$$\mathbb{E} \left\| \sum_{i=1}^l X_i(x) - \frac{g(x)l}{\|g\|_{A(G)}} \right\|^p = O(pl)^{p/2}.$$

We integrate the above against μ_1^+ (recall this is one of the family of measures provided by the hypothesis that μ is B -approximately invariant) and rearrange so that

$$\mathbb{E} \left\| \|g\|_{A(G)} \frac{1}{l} \sum_{i=1}^l X_i - g \right\|_{L_p(\mu_1^+)}^p = O(pl^{-1} \|g\|_{A(G)}^2)^{p/2}.$$

Now, take $l = O(\epsilon^{-2}p)$ such that the right hand side rescaled is at most $\left(\frac{\epsilon \|g\|_{A(G)}}{4\sqrt{2}}\right)^p$. It follows that there are characters $\gamma_1, \dots, \gamma_l$ such that

$$\|f - g\|_{L_p(\mu_1^+)} \leq \frac{\epsilon \|g\|_{A(G)}}{4\sqrt{2}} \text{ where } f := \|g\|_{A(G)} \cdot \frac{1}{l} \sum_{i=1}^l \frac{\widehat{g}(\gamma_i)}{|\widehat{g}(\gamma_i)|} \gamma_i.$$

Since $\|f\|_{A(G)} \leq \|g\|_{A(G)}$ (by the triangle inequality) we may apply Lemma 6.1 to the set of character $\{\gamma_1, \dots, \gamma_l\}$ to get a Bohr system B'' with $\mathcal{C}^\Delta(G; B_1'') \leq 1$ and $\dim B'' = O(l) = O(\epsilon^{-2}p)$ such that

$$\|\tau_x(f) - f\|_{L_\infty(G)} \leq \frac{\epsilon \|g\|_{A(G)}}{2} \text{ for all } x \in B'_{\frac{1}{2\pi}\epsilon}.$$

If $x \in B_1$ then by the approximate invariance of μ we have $\tau_x(\mu) \leq 2\mu_1^+$ and $\mu \leq 2\mu_1^+$, and so by the triangle inequality we have

$$\begin{aligned} \|\tau_x(g) - g\|_{L_p(\mu)} &\leq \|\tau_x(g) - \tau_x(f)\|_{L_p(\mu)} + \|\tau_x(f) - f\|_{L_p(\mu)} + \|f - g\|_{L_p(\mu)} \\ &= \|g - f\|_{L_p(\tau_{-x}(\mu))} + \|\tau_x(f) - f\|_{L_p(\mu)} + \|f - g\|_{L_p(\mu)} \\ &\leq 2 \cdot 2^{\frac{1}{p}} \|g - f\|_{L_p(\mu_1^+)} + \|\tau_x(f) - f\|_{L_\infty(G)}. \end{aligned}$$

We conclude that

$$\|\tau_x(g) - g\|_{L_p(\mu)} \leq 2 \cdot 2^{1/p} \cdot \frac{\epsilon \|g\|_{A(G)}}{4\sqrt{2}} + \frac{\epsilon \|g\|_{A(G)}}{2} \leq \epsilon \|g\|_{A(G)} \text{ whenever } x \in B_1 \cap B''_{\frac{1}{2\pi}\epsilon}.$$

Put $B' := B \wedge ((\frac{1}{2\pi}\epsilon)B'')$ and note by Lemma 3.7 parts (i) and (ii), and the earlier bound on $\dim B''$ that

$$\dim B' \leq \dim B + \dim \left(\left(\frac{1}{2\pi}\epsilon \right) B'' \right) \leq \dim B + \dim B'' = \dim B + O(p\epsilon^{-2});$$

and by Lemma 2.4 part (ii) and Lemma 3.8 part (i) and the bounds on B'' we have

$$\begin{aligned} \mathcal{C}^\Delta(A; B'_1) &= \mathcal{C}^\Delta \left(A \cap G; B_1 \cap \left(\left(\frac{1}{2\pi}\epsilon \right) B'' \right)_1 \right) \\ &\leq \mathcal{C}^\Delta(A; B_1) \mathcal{C}^\Delta \left(G; \left(\left(\frac{1}{2\pi}\epsilon \right) B'' \right)_1 \right) \\ &\leq \mathcal{C}^\Delta(A; B_1) (8\pi\epsilon^{-1})^{\dim B''} \mathcal{C}^\Delta(G; B''_1) \leq \mathcal{C}^\Delta(A; B_1) (2\epsilon^{-1})^{O(p\epsilon^{-2})}. \end{aligned}$$

The result is proved. \square

7. QUANTITATIVE CONTINUITY

It is well known that if G is a locally compact Abelian group and $f \in A(G)$ then f is uniformly continuous. If G is finite then this statement has no content – every function on G is uniformly continuous – but in the paper [GK09], Konyagin and Green proved a statement which can be thought of as a quantitative version of this fact which still has content for finite Abelian groups. The main purpose of this section is to prove the following result of this type using essentially their method.

Proposition 7.1. *Suppose that $A \subset G$, B is a Bohr system of dimension at most d (for some $d \geq 1$), $f \in A(G)$, and $\delta, \kappa \in (0, 1]$ and $p \geq 2$ are parameters. Then there is a Bohr system $B' \leq B$ with*

$$\mathcal{C}^\Delta(A; B'_1) \leq \exp(O(\delta^{-1}d \log 2\kappa^{-1}d + p\delta^{-3} \log^3 2p\kappa^{-1}\delta^{-1})) \mathcal{C}^\Delta(A; B_1)$$

and

$$\dim B' \leq d + O(p\delta^{-2} \log^2 2\delta^{-1}),$$

and a B' -approximately invariant probability measure μ and a probability measure ν supported on B'_κ such that

$$\sup_{x \in G} \|f - f * \mu\|_{L_p(\tau_x(\nu))} \leq \delta \|f\|_{A(G)}.$$

We shall prove Proposition 7.1 iteratively using the following lemma (which is, itself, proved iteratively).

Lemma 7.2. *Suppose that $A \subset G$, B is a Bohr system of dimension at most d (for some $d \geq 1$), ν is a B -approximately invariant probability measure, μ is a probability measure supported on a set X , $f \in A(G)$ and $\delta, \eta \in (0, 1]$ and $p \geq 2$ are parameters. Then at least one of the following is true:*

(i) we have

$$\sup_{x \in G} \|f - f * \mu\|_{L_p(\tau_x(\nu))} \leq \delta \|f\|_{A(G)};$$

(ii) there is some $1 \geq \rho = \Omega(\delta)$ and a Bohr system $B' \leq B$ with

$$\mathcal{C}^\Delta(A; B'_1) \leq \exp(O(p\rho^2\delta^{-2}\log^3 2p\delta^{-1} + d\log d))\mathcal{C}^\Delta(A; B_1)$$

and

$$\dim B' \leq \dim B + O(p\rho^2\delta^{-2}\log^2 2\delta^{-1}),$$

such that

$$\sum_{\gamma \in N(B'_{2^{-7}\delta\eta}, \eta) \setminus N(X, 2^{-5}\delta)} |\hat{f}(\gamma)| \geq \rho \|f\|_{A(G)}.$$

Proof. Since the hypotheses and conclusions are invariant under translation by x it suffices to prove that if

$$(7.1) \quad \|f - f * \mu\|_{L_p(\nu)} > \delta \|f\|_{A(G)},$$

then we are in the second case of the lemma.

Let $\kappa := \lceil \log_2 8\delta^{-1} \rceil^{-1}$ for reasons which will become clear later; at this stage it suffices to note that $\kappa \in (0, 1/2]$. Define $\delta_i := (1 - \kappa)^i \delta$ for integers i with $0 \leq i \leq \kappa^{-1}$ and put $g_0 := f - f * \mu$. Suppose that we have defined a function g_i such that

$$\|g_i\|_{L_p(\nu)} > \delta_i \|f\|_{A(G)}, \|g_i\|_{A(G)} \leq 2^{1-i} \|f\|_{A(G)} \text{ and } g_i = g_0 * \mu_i$$

for some probability measure μ_i . By taking μ_0 to be the delta probability measure assigning mass 1 to 0_G , we see from (7.1) that g_i satisfies these hypotheses for $i = 0$.

By Lemma 6.2 applied to the function g_i , the Bohr system B and measure ν with parameters p and $\epsilon_i := \kappa \|g_i\|_{L_p(\nu)} \|g_i\|_{A(G)}^{-1}$, there is a Bohr system $B^{(i)}$ with

$$(7.2) \quad \mathcal{C}^\Delta(A; B_1^{(i)}) \leq \exp(O(p\epsilon_i^{-2} \log 2\epsilon_i^{-1}))\mathcal{C}^\Delta(A; B_1)$$

and

$$(7.3) \quad \dim B^{(i)} \leq \dim B + O(p\epsilon_i^{-2})$$

such that

$$\|\tau_x(g_i) - g_i\|_{L_p(\nu)} \leq \kappa \|g_i\|_{L_p(\nu)} \text{ for all } x \in B_1^{(i)}.$$

By Corollary 4.5 applied to $B^{(i)}$ there is some $1 \geq \lambda_i = \Omega((1 + \dim B^{(i)})^{-1})$ and a $\lambda_i B^{(i)}$ -approximately invariant probability measure $\nu^{(i)}$ supported on $B_1^{(i)}$. Integrating (and applying the integral triangle inequality) we conclude that

$$\|g_i - g_i * \nu^{(i)}\|_{L_p(\nu)} \leq \kappa \|g_i\|_{L_p(\nu)},$$

and so by the triangle inequality and hypothesis on g_i we have

$$\|g_i * \nu^{(i)}\|_{L_p(\nu)} \geq \|g_i\|_{L_p(\nu)} - \kappa \|g_i\|_{L_p(\nu)} > \delta_{i+1} \|f\|_{A(G)}.$$

Put $g_{i+1} := g_i * \nu^{(i)}$ and $\mu_{i+1} = \mu_i * \nu^{(i)}$. If $\|g_{i+1}\|_{A(G)} \leq 2^{1-(i+1)}\|f\|_{A(G)}$ then repeat; otherwise terminate the iteration. Since $x \mapsto (1-x)^{x^{-1}}$ is monotonically decreasing for all $x \in (0, 1]$ we see that if $i \leq \kappa^{-1}$ then

$$(7.4) \quad \begin{aligned} \frac{1}{4}\delta\|f\|_{A(G)} &\leq (1-\kappa)^{\kappa^{-1}}\delta\|f\|_{A(G)} \leq (1-\kappa)^i\delta\|f\|_{A(G)} \\ &\leq \delta_i\|f\|_{A(G)} < \|g_i\|_{L_p(\nu)} \leq \|g_i\|_{A(G)} \end{aligned}$$

Given our choice of κ we see that $2^{1-\kappa^{-1}}\|f\|_{A(G)} \leq \frac{1}{4}\delta\|f\|_{A(G)}$ and so it follows from (7.4) that there is some minimal $i \leq \kappa^{-1}$ such that $\|g_i\|_{A(G)} > 2^{1-i}\|f\|_{A(G)}$. In particular $2^{-i} \geq 2^{-4}\delta$.

By choice of i , construction of μ_i , and definition of g_0 we have

$$\begin{aligned} 2^{1-i}\|f\|_{A(G)} &\leq \|g_i\|_{A(G)} = \|g_0 * \mu_{i-1} * \nu^{(i-1)}\|_{A(G)} \\ &= \sum_{\gamma \in \widehat{G}} |\widehat{f}(\gamma)| |1 - \widehat{\mu}(\gamma)| |\widehat{\nu^{(i-1)}}(\gamma)| |\widehat{\mu_{i-1}}(\gamma)| \\ &\leq \sum_{\gamma \in \widehat{G}} |\widehat{f}(\gamma)| |1 - \widehat{\mu}(\gamma)| |\widehat{\nu^{(i-1)}}(\gamma)|. \end{aligned}$$

Hence

$$\begin{aligned} &\sum_{\substack{|\widehat{\nu^{(i-1)}}(\gamma)| > 2^{-6}\delta \\ |1-\gamma(x)| \geq 2^{-5}\delta \text{ for some } x \in X}} |\widehat{f}(\gamma)| |1 - \widehat{\mu}(\gamma)| |\widehat{\nu^{(i-1)}}(\gamma)| \\ &+ \sum_{|1-\gamma(x)| < 2^{-5}\delta \text{ for all } x \in X} |\widehat{f}(\gamma)| |1 - \widehat{\mu}(\gamma)| |\widehat{\nu^{(i-1)}}(\gamma)| \\ &+ \sum_{|\widehat{\nu^{(i-1)}}(\gamma)| \leq 2^{-6}\delta} |\widehat{f}(\gamma)| |1 - \widehat{\mu}(\gamma)| |\widehat{\nu^{(i-1)}}(\gamma)| \\ &\geq \sum_{\gamma \in \widehat{G}} |\widehat{f}(\gamma)| |1 - \widehat{\mu}(\gamma)| |\widehat{\nu^{(i-1)}}(\gamma)|. \end{aligned}$$

If $\gamma \in \widehat{G}$ is such that $|1 - \gamma(x)| < 2^{-5}\delta$ for all $x \in X$, then by the triangle inequality $|1 - \widehat{\mu}(\gamma)| \leq 2^{-5}\delta$, and hence the second sum on the left is at most $2^{-5}\delta\|f\|_{A(G)}$. Since $|1 - \widehat{\mu}(\gamma)| \leq 2$ by the triangle inequality, the third sum on the left is at most $2\|f\|_{A(G)} \cdot 2^{-6}\delta$, and so by the triangle inequality we have

$$\begin{aligned} &\sum_{\substack{|\widehat{\nu^{(i-1)}}(\gamma)| > 2^{-6}\delta \\ |1-\gamma(x)| \geq 2^{-5}\delta \text{ for some } x \in X}} |\widehat{f}(\gamma)| |1 - \widehat{\mu}(\gamma)| |\widehat{\nu^{(i-1)}}(\gamma)| \geq 2^{1-i}\|f\|_{A(G)} - 2^{-4}\delta\|f\|_{A(G)} \\ &\geq 2^{1-i}\|f\|_{A(G)} - 2^{-i}\|f\|_{A(G)} = 2^{-i}\|f\|_{A(G)}. \end{aligned}$$

Put $B' := \lambda_i B^{(i)}$ and apply Lemma 5.2 to $\nu^{(i-1)}$ and B' with parameters $2^{-6}\delta$ and η to see that

$$\begin{aligned} \{\gamma : |\widehat{\nu^{(i-1)}}(\gamma)| > 2^{-6}\delta \text{ and } |1 - \gamma(x)| \geq 2^{-5}\delta \text{ for some } x \in X\} \\ \subset N(B'_{2^{-7}\delta\eta}, \eta) \setminus N(X, 2^{-5}\delta). \end{aligned}$$

Writing $\rho := 2^{-i-1} = \Omega(\delta)$ and recalling that $|1 - \widehat{\mu}(\gamma)| |\widehat{\nu^{(i-1)}}(\gamma)| \leq 2$ by the triangle inequality we have

$$\sum_{\gamma \in N(B'_{2^{-7}\delta\eta}, \eta) \setminus N(X, 2^{-5}\delta)} |\widehat{f}(\gamma)| \geq \rho \|f\|_{A(G)}.$$

It remains to note that $\epsilon_i > \kappa \delta_i 2^{i-1} = \Omega(\kappa \delta \rho^{-1})$ and so by Lemma 3.7 part (ii), and (7.3) we see that $\dim B'$ satisfies the claimed bound. Finally, by Lemma 3.8 part (i), (7.2), (7.3), and the lower bound on λ_i we have

$$\begin{aligned} \mathcal{C}^\Delta(A; B'_1) &= \mathcal{C}^\Delta(A; B_{\lambda_i}^{(i)}) \\ &\leq (4\lambda_i^{-1})^{\dim B^{(i)}} \mathcal{C}^\Delta(A; B_1^{(i)}) \\ &\leq (4\lambda_i^{-1})^{\dim B^{(i)}} \exp(O(p\epsilon_i^{-2} \log 2\epsilon^{-1})) \mathcal{C}^\Delta(A; B_1) \\ &\leq d^{O(d)} \exp(O(p\rho^2 \delta^{-2} \log 2p\delta^{-1})) \mathcal{C}^\Delta(A; B_1), \end{aligned}$$

from which the lemma follows. \square

Proof of Proposition 7.1. We proceed iteratively constructing Bohr systems $(B^{(i)})_{i=0}^J$ and reals $(\rho_i)_{i=1}^J$, and $(d_i)_{i=0}^J$, such that

- (i) $B^{(i+1)} \leq B^{(i)}$;
- (ii) $1 \geq \rho_i = \Omega(\delta)$ and

$$\sum_{N(B_1^{(i+1)}, 2^{-5}\delta) \setminus N(B_1^{(i)}, 2^{-5}\delta)} |\widehat{f}(\gamma)| \geq \rho_i \|f\|_{A(G)};$$

(iii)

$$\mathcal{C}^\Delta(A; B_1^{(i+1)}) \leq \exp(O(p\rho_i^2 \delta^{-2} \log^3 2p\delta^{-1} + d_i \log \kappa^{-1} d_i)) \mathcal{C}^\Delta(A; B_1^{(i)});$$

(iv)

$$d_{i+1} \leq d_i + O(p\rho_i^2 \delta^{-2} \log^2 2\delta^{-1}).$$

We initialise with $B^{(0)} := B$ and $d_0 := d$. Suppose that we are at stage i of the iteration. Apply Corollary 4.5 to $B^{(i)}$ to get some $\lambda_i = \Omega((1 + \dim B^{(i)})^{-1})$ and a $\lambda_i B^{(i)}$ -approximately invariant probability measure μ_i supported on $B_1^{(i)}$. Apply Corollary 4.5 to $\kappa \lambda_i B^{(i)}$ to get some

$$\lambda'_i = \Omega((1 + \dim \kappa \lambda_i B^{(i)})^{-1}) = \Omega(d_i^{-1})$$

and a $\lambda'_i \kappa \lambda_i B^{(i)}$ -approximately invariant probability measure ν_i supported on $\kappa \lambda_i B^{(i)}$.

By Lemma 3.7 part (ii) we see that

$$\dim \lambda'_i \kappa \lambda_i B^{(i)} \leq \dim B^{(i)} \leq d_i.$$

Apply Lemma 7.2 to A , $\lambda'_i \kappa \lambda_i B^{(i)}$, d_i , ν_i , μ_i , $B_1^{(i)}$ and f with parameters δ and $2^{-5}\delta$ (and p).

CASE 1: If we are in the first case of the lemma then we terminate the iteration and put $B' := \lambda_i B^{(i)}$, $\mu := \mu_i$ and $\nu := \nu_i$, so that

$$\sup_{x \in G} \|f - f * \mu\|_{L_p(\tau_x(\nu))} \leq \delta \|f\|_{A(G)}.$$

By Lemma 3.8 part (i) we see that

$$(7.5) \quad \begin{aligned} \mathcal{C}^\Delta(A; B'_1) &= \mathcal{C}^\Delta(A; B_{\lambda_i}^{(i)}) \\ &\leq (4\lambda_i^{-1})^{\dim B^{(i)}} \mathcal{C}^\Delta(A; B_1^{(i)}) \leq \exp(O(d_i \log 2d_i)) \mathcal{C}^\Delta(A; B_1^{(i)}); \end{aligned}$$

and by Lemma 3.7 part (ii) we have

$$(7.6) \quad \dim B' = \dim \lambda_i B^{(i)} \leq \dim B^{(i)} \leq d_i.$$

Once we have estimated d_i and $\mathcal{C}^\Delta(A; B_1^{(i)})$ we shall be done.

CASE 2: If we are not in the first case of the lemma then there is some $\rho_i = \Omega(\delta)$ and a Bohr system $B^{(i,1)} \leq \lambda'_i \kappa \lambda_i B^{(i)}$ such that

$$(7.7) \quad \dim B^{(i,1)} \leq \dim \lambda'_i \kappa \lambda_i B^{(i)} + O(p\rho_i^2 \delta^{-2} \log^2 \delta^{-1});$$

and

$$\mathcal{C}^\Delta(A; B_1^{(i,1)}) \leq \exp(O(p\rho_i^2 \delta^{-2} \log^3 2p\delta^{-1} + d_i \log d_i)) \mathcal{C}^\Delta(A; (\lambda'_i \kappa \lambda_i B^{(i)})_1).$$

However,

$$\mathcal{C}^\Delta(A; (\lambda'_i \kappa \lambda_i B^{(i)})_1) = \mathcal{C}^\Delta(A; B_{\lambda'_i \kappa \lambda_i}^{(i)}) \leq (4\lambda_i^{-1}(\lambda'_i)^{-1}\kappa^{-1})^{\dim B^{(i)}} \mathcal{C}^\Delta(A; B_1^{(i)}),$$

by Lemma 3.8 part (i). Thus

$$\mathcal{C}^\Delta(A; B_1^{(i,1)}) \leq \exp(O(p\rho_i^2 \delta^{-2} \log^3 2p\delta^{-1} + d_i \log \kappa^{-1} d_i)) \mathcal{C}^\Delta(A; B_1^{(i)}).$$

Additionally we have

$$\sum_{N(B_{2^{-12}\delta^2}^{(i,1)}, 2^{-5}\delta) \setminus N(B_1^{(i)}, 2^{-5}\delta)} |\hat{f}(\gamma)| \geq \rho_i.$$

Put $B^{(i+1)} := (2^{-12}\delta^2)B^{(i,1)}$ and we get (ii). Moreover,

$$B^{(i+1)} = (2^{-12}\delta^2)B^{(i,1)} \leq B^{(i,1)} \leq \lambda'_i \kappa \lambda_i B^{(i)} \leq B^{(i)}$$

by the order preserving nature of dilation and the fact that $2^{-12}\delta \leq 1$ and $\lambda'_i \kappa \lambda_i \leq 1$; it follows that we have (i). Now, Lemma 3.7 part (ii) and (7.7) gives

$$\begin{aligned} \dim B^{(i+1)} &= \dim(2^{-12}\delta^2)B^{(i,1)} \leq \dim B^{(i,1)} \leq \dim \lambda'_i \kappa \lambda_i B^{(i)} + O(p\rho_i^2 \delta^{-2} \log^2 \delta^{-1}) \\ &\leq \dim B^{(i)} + O(p\rho_i^2 \delta^{-2} \log^2 \delta^{-1}) \\ &\leq d_i + O(p\rho_i^2 \delta^{-2} \log^2 \delta^{-1}), \end{aligned}$$

from which we get (iv). Finally, Lemma 3.8 part (i) tells us that

$$\begin{aligned} \mathcal{C}^\Delta(A; B_1^{(i+1)}) &= \mathcal{C}^\Delta(A; B_{2^{-12}\delta^2}^{(i,1)}) \\ &\leq (2^{14}\delta^{-2})^{\dim B^{(i,1)}} \mathcal{C}^\Delta(A; B_1^{(i,1)}) \\ &\leq \exp(O(p\rho_i^2\delta^{-2}\log^3 2p\delta^{-1} + d_i \log \kappa^{-1}d_i)) \mathcal{C}^\Delta(A; B_1^{(i)}), \end{aligned}$$

from which we get (iii).

In the light of (i) we see that $B_1^{(i+1)} \subset B_1^{(i)}$ and hence

$$N(B_1^{(i+1)}, 2^{-5}\delta) \supset N(B_1^{(i)}, 2^{-5}\delta).$$

It follows that after i steps we have

$$\|f\|_{A(G)} \geq \sum_{N(B_1^{(i)}, 2^{-5}\delta)} |\hat{f}(\gamma)| \geq \sum_{j \leq i} \rho_j \|f\|_{A(G)}.$$

It follows that

$$\sum_{j \leq i} \rho_j \leq 1.$$

Since $\rho_j = \Omega(\delta)$ we conclude that we must be in **CASE 2** at some step $J = O(\delta^{-1})$ of the iteration. In light of (iv) we see that

$$d_i \leq d + O(p\delta^{-2}\log^2 2\delta^{-1}) \text{ for all } i \leq J.$$

It follows that

$$\begin{aligned} \mathcal{C}^\Delta(A; B_1^{(J)}) &\leq \left(\prod_{j < J} \exp(O(p\rho_j^2\delta^{-2}\log^3 2p\delta^{-1} + d_j \log \kappa^{-1}d_j)) \right) \mathcal{C}^\Delta(A; B_1) \\ &\leq \exp(O(Jd \log 2\kappa^{-1}d + Jp\delta^{-2}\log^3 2p\kappa^{-1}\delta^{-1})) \mathcal{C}^\Delta(A; B_1). \end{aligned}$$

The result is proved on inserting these bounds into (7.5) and (7.6). \square

8. A FREĬMAN-TYPE THEOREM

The purpose of this section is to prove the following proposition, which is a routine if slightly fiddly variation on existing material in the literature.

Proposition 8.1. *Suppose that A is non-empty and $m_G(A + A) \leq Km_G(A)$. Then there is a Bohr system B with*

$$\mathcal{C}^\Delta(A; B_1) = \exp(O(\log^3 2K(\log 2 \log 2K)^4))$$

and

$$\dim B = O(\log^3 2K(\log 2 \log 2K)^4),$$

such that

$$(8.1) \quad \|1_A * \beta\|_{L_\infty(G)} = \exp(-O(\log 2K(\log 2 \log 2K)))$$

for any probability measure β supported on B_1 .

The proposition itself is closely related to Freĭman's theorem and we refer the reader to [TV06, Chapter 5] for a discussion of Freĭman's theorem. For our purposes there are two key differences:

- (i) Freĭman's theorem is usually only stated with the first two conclusions. It is possible to infer the fact that

$$\|1_A * \beta\|_{L_\infty(G)} = \exp(-O(\log^3 2K(\log 2 \log 2K)^4))$$

for any probability measure β supported on B_1 from the bound on $\mathcal{C}^\Delta(A; B_1)$, and the fact that one can do better and get (8.1) in this sort of situation is an unpublished observation of Green and Tao.

- (ii) Freĭman's theorem also produces a coset progression rather than a Bohr system. A set M is a **d -dimensional coset progression** if there are arithmetic progressions P_1, \dots, P_d and a subgroup H such that $M = P_1 + \dots + P_d + H$. This definition was made by Green and Ruzsa in [GR07] when they gave the first proof of Freĭman's theorem for Abelian groups. The conclusion of Freĭman's theorem then is that there is a coset progression M with

$$\mathcal{C}^\Delta(A; M) = O_K(1) \text{ and } \dim M = O_K(1),$$

and the challenge is to identify good estimates for the $O_K(1)$ -terms.

For us it is the quantitative aspects of Proposition 8.1 that are important. The quantitative aspects of Freĭman's theorem are surveyed in [San13], and primarily arise from the quantitative strength of the Croot-Sisask Lemma (in particular the m -dependence in [CS10, Proposition 3.3]), but also some combinatorial arguments of Konyagin [Kon11] discussed just before [San13, Corollary 8.4]. Conjecturally all the big- O terms should be $O(\log 2K)$, though the proof below does not come close to that. It could probably be tightened up to same on the power of $\log 2 \log 2K$ in the first two estimates above, at least reducing the 4 to a 3 but quite possible further.

We shall prove Proposition 8.1 as a combination of the next three results which we shall show in §8.5, §8.10, and §8.11 respectively. We say that a set X has **relative polynomial growth of order d** if

$$m_G(nX) \leq n^d m_G(X) \text{ for all } n \geq 1.$$

The first result can be read out of the proof of [San13, Proposition 2.5] and essentially captures the power of the Croot-Sisask Lemma for our purposes.

Lemma 8.2. *Suppose that A is non-empty with $m_G(A + A) \leq K m_G(A)$. Then there is a symmetric neighbourhood of the identity X of relative polynomial growth of order $O(\log^3 2K(\log 2 \log 2K)^3)$ and*

$$m_G(X) \geq \exp(-O(\log^3 2K(\log 2 \log 2K)^3)) m_G(A),$$

and some naturals $m = \Omega(\log 2K(\log 2 \log 2K))$ and $r = O(\log 2 \log 2K)$ such that $mX \subset r(A - A)$.

The second result is one we have already touched on and captured a key insight of Green and Ruzsa in [GR07] that allows passage from relative polynomial growth to structure.

Lemma 8.3. *Suppose that X is a symmetric non-empty set with relative polynomial growth of order $d \geq 1$. Then there is a Bohr system B with*

$$\dim B = O(d) \text{ and } m_G(B_1) = d^{O(d)} m_G(X).$$

such that $X - X \subset B_1$.

Finally the last lemma is a development of a result of Bogoliouboff [Bog39] revived for this setting by Ruzsa [Ruz94], and then refined by Chang [Cha02].

Lemma 8.4. *Suppose that A is a non-empty set, B is a Bohr system and μ is a B -approximately invariant probability measure, $S \subset B_1$ has $\mu(S) > 0$, and L , non-empty, is such that $\|1_L * \mu_S\|_{L_2(m_G)}^2 \geq \epsilon m_G(L)$. Then there is a Bohr system $B' \leq B$ with*

$$\mathcal{C}^\Delta(A; B'_1) \leq (2\epsilon^{-1})^{O(\epsilon^{-2} \log 2\mu(S)^{-1})} \mathcal{C}^\Delta(A; B_1)$$

and

$$\dim B' = \dim B + O(\epsilon^{-2} \log 2\mu(S)^{-1})$$

such that $B'_1 \subset L - L + S - S$.

With these results in hand we can turn to proving the main result of the section.

Proof of Proposition 8.1. We apply Lemma 8.2 to A to get a non-empty symmetric set X of relative polynomial growth of order $O(\log 2K \log 2 \log 2K)^3$ with

$$(8.2) \quad m_G(X) \geq \exp(-O(\log 2K \log 2 \log 2K)^3) m_G(A),$$

and natural numbers $m = \Omega(\log 2K \log 2 \log 2K)$ and $r = O(\log 2 \log 2K)$ such that $mX \subset r(A - A)$. By Lemma 8.3 there is a Bohr system B' with $X - X \subset B'_1$ such that

$$\dim B' = O(\log 2K \log 2 \log 2K)^3 \text{ and } m_G(B'_1) \leq \exp(O(\log^3 2K (\log 2 \log 2K)^4)) m_G(X).$$

By nesting of Bohr we have that

$$\mathcal{C}^\Delta(X - X; B'_1) \leq \mathcal{C}^\Delta(B'_1; B'_1) \leq \mathcal{C}^\Delta\left(B'_1; B'_{\frac{1}{2}}\right) \leq 2^{\dim B'} = \exp(O(\log 2K \log 2 \log 2K)^3).$$

By Corollary 4.5 there is a probability measure μ and a Bohr system $B'' = \lambda B'$ for some $\lambda = \Omega((1 + \dim B')^{-1})$ such that μ is supported on B'_1 and μ is B'' -approximately invariant. By Lemma 3.8 part (i) (with reference set $X - X$) we have

$$\mathcal{C}^\Delta(X - X; B''_1) \leq (4\lambda^{-1})^{\dim B''} \mathcal{C}^\Delta(X - X; B'_1) \leq \exp(O(\log^3 2K (\log 2 \log 2K)^4)).$$

By the second inequality in Lemma 3.7 part (iii) and the definition of dimension there is a set T with

$$|T| \leq 2^{2^{\dim^* B'}} = \exp(O(\log 2K \log 2 \log 2K)^3) \text{ and } B'_1 \subset T + B'_{\frac{1}{2}}.$$

It follows from nesting of Bohr sets that

$$B'_1 + B'_1 \subset T + T + B'_{\frac{1}{2}} + B'_{\frac{1}{2}} \subset T + T + B'_1.$$

Now, since $\text{supp } \mu \subset B'_1$ we see that $1_{B'_1+B'_1} * \mu(x) = 1$ for all $x \in B'_1$ and so (since $0_G \in X$) we have

$$\begin{aligned} m_G(X) &\leq \langle 1_X, 1_{B'_1+B'_1} * \mu \rangle_{L_2(m_G)} \\ &\leq \sum_{t \in T-T} \langle 1_X * \mu, 1_{t+B'_1} \rangle_{L_2(m_G)} \leq |T-T| \sup_{x \in G} \mu(x+X) m_G(B'_1). \end{aligned}$$

Inserting the upper bound for $m_G(B'_1)$ and the upper bound for $|T|$, it follows that there is some x such that

$$\mu(x+X) \geq \exp(-O(\log^3 2K(\log 2 \log 2K)^4)).$$

Now, put $S := x + X$ and note from Plünnecke's inequality that

$$\begin{aligned} \prod_{l=0}^{m-1} \frac{m_G(A - A + lS + S)}{m_G(A - A + lS)} &= \prod_{i=0}^{m-1} \frac{m_G(A - A + lX + X)}{m_G(A - A + lX)} \\ &= \frac{m_G(A - A + mX)}{m_G(A - A)} \leq K^{2(r+1)}. \end{aligned}$$

Given the lower bound on m and upper bound on r it follows that there is some $0 \leq l \leq m-1$ such that

$$m_G(A - A + lS + S) \leq K^{\frac{2(r+1)}{m}} m_G(A - A + lS) = O(m_G(A - A + lS)).$$

Putting $L := A - A + lS$ it follows by the Cauchy-Schwarz inequality that

$$\|1_L * \mu_S\|_{L_2(m_G)}^2 \geq \frac{m_G(L)^2}{m_G(L+S)} = \Omega(m_G(L)).$$

By Lemma 8.4 (with reference set $X - X$) we then see that there is a Bohr system $B \leq B''$ with

$$\begin{aligned} \mathcal{C}^\Delta(X - X; B_1) &\leq \exp(O(\log^3 2K(\log 2 \log 2K)^4)) \mathcal{C}^\Delta(X - X; B''_1) \\ (8.3) \quad &\leq \exp(O(\log^3 2K(\log 2 \log 2K)^4)) \end{aligned}$$

and

$$\dim B = \dim B'' + O(\log^3 2K(\log 2 \log 2K)^4) = O(\log^3 2K(\log 2 \log 2K)^4),$$

such that

$$\begin{aligned} B_1 &\subset S + L - L - S \subset 2(A - A) + (l+1)(S - S) \\ &= 2(A - A) + 2(l+1)X \subset (2r+1)(A - A). \end{aligned}$$

Since $0_G \in X$ we see that $X \subset r(A - A)$ and hence by Lemma 2.5 and Plünnecke's inequality (and (8.2) and (8.3)) we have

$$\begin{aligned} \mathcal{C}^\Delta(A; B_1) &\leq \frac{m_G(A + X)}{m_G(X)} \mathcal{C}^\Delta(X - X; B_1) \\ &\leq \frac{K^{r+1} m_G(A)}{\exp(-O(\log^3 2K \log 2 \log 2K)^3) m_G(A)} \exp(O(\log^3 2K (\log 2 \log 2K)^4)) \\ &= \exp(O(\log^3 2K (\log 2 \log 2K)^4)). \end{aligned}$$

Finally, if β is supported on B_1 then

$$m_G(A) \leq \langle 1_A * \beta, 1_{A+4r(A-A)} \rangle_{L_2(m_G)} \leq \|1_A * \beta\|_{L_\infty(G)} m_G(A + 4r(A - A))$$

from which the final bound follows by Plünnecke's inequality. \square

8.5. Croot-Sisask Lemma arguments. The aim of this section is to prove the following lemma.

Lemma (Lemma 8.2). *Suppose that A is non-empty with $m_G(A + A) \leq K m_G(A)$. Then there is a symmetric neighbourhood of the identity X of relative polynomial growth of order $O(\log^3 2K (\log 2 \log 2K)^3)$ and*

$$m_G(X) \geq \exp(-O(\log^3 2K (\log 2 \log 2K)^3)) m_G(A),$$

and some naturals $m = \Omega(\log 2K (\log 2 \log 2K))$ and $r = O(\log 2 \log 2K)$ such that $mX \subset r(A - A)$.

The material follows the proof of [San13, Proposition 8.5] very closely, though we shall need some minor modifications. We start by recording two results used to prove that proposition.

Corollary 8.6 ([San13, Corollary 5.3]). *Suppose that $X \subset G$ is a symmetric neighbourhood and $m_G((3k+1)X) < 2^k m_G(X)$ for some $k \in \mathbb{N}$. Then X has relative polynomial growth of order $O(k)$.*

This is just a variant of Chang's covering lemma from [Cha02] (see also [TV06, Lemma 5.31]).

Lemma 8.7 (Croot-Sisask, [San13, Lemma 7.1]). *Suppose that $f \in L_p(m_G)$ for some $p \in [2, \infty)$, $S, T \subset G$ are non-empty such that $m_G(S + T) \leq L m_G(S)$, and $\eta \in (0, 1]$ is a parameter. Then there is a symmetric neighbourhood of the identity X with*

$$m_G(X) \geq (2L)^{-O(\eta^{-2p})} m_G(T)$$

such that

$$\|\tau_x(f * m_S) - f * m_S\|_{L_p(m_G)} \leq \eta \|f\|_{L_p(m_G)} \text{ for all } x \in X.$$

This captures the content of the Croot-Sisask Lemma [CS10, Proposition 3.3] for our purposes.

We shall also need a slight variant of [San13, Proposition 8.3].

Proposition 8.8. *Suppose that A, S and T are non-empty with $m_G(A + S) \leq Km_G(A)$ and $m_G(S + T) \leq Lm_G(S)$, and $m \in \mathbb{N}$ is a parameter. Then there is a symmetric neighbourhood of the identity, X , with*

$$m_G(X) \geq \exp(-O(m^2 \log 2K \log 2L))m_G(T) \text{ and } mX \subset S + A - A - S.$$

Proof. Let $f := 1_{A+S}$ and apply the Croot-Sisask lemma (Lemma 8.7) with a parameters η and p (to be optimised later) to get a symmetric neighbourhood of the identity, X , with $m_G(X) \geq (2L)^{-O(\eta^{-2}p)}m_G(T)$ such that

$$\|\tau_x(1_{A+S} * m_{-S}) - 1_{A+S} * m_{-S}\|_{L_p(m_G)} \leq \eta \|1_{A+S}\|_{L_p(m_G)} \text{ for all } x \in X.$$

It follows by the triangle inequality that

$$\|\tau_x(1_{A+S} * m_{-S}) - 1_{A+S} * m_{-S}\|_{L_p(m_G)} \leq \eta m \|1_{A+S}\|_{L_p(m_G)} \text{ for all } x \in mX.$$

Taking an inner product with m_A we see that for all $x \in X$ we have

$$|\langle \tau_x(1_{A+S} * m_{-S}), m_A \rangle - \langle 1_{A+S} * m_{-S}, m_A \rangle| \leq \eta m \|1_{A+S}\|_{L_p(m_G)} \|m_A\|_{L_{p'}(m_G)}$$

where p' is the conjugate exponent to p . Now

$$\langle 1_{A+S} * m_{-S}, m_A \rangle = \langle 1_{A+S}, m_A * m_S \rangle = 1.$$

Thus

$$|m_A * 1_{-(A+S)} * m_S(x) - 1| \leq \eta m K^{1/p} \text{ for all } x \in X.$$

We take $p = 2 + \log K$, and then $\eta = \Omega(m^{-1})$ such that the term on the right is at most $1/2$ to get the desired conclusion. \square

The above proposition is almost all we need for our main argument and it can be used in the proof of Lemma 8.2 below to give a result with only slightly weaker bounds. However, we shall want a slight strengthening proved using the aforementioned idea of Konyagin [Kon11].

Proposition 8.9. *Suppose that A is non-empty with $m_G(A + A) \leq Km_G(A)$ and $r, s \in \mathbb{N}$ are parameters with $r \geq 3$. Then there is an integer $m = \Omega(sr \log^{1-O(r^{-1})} 2K)$ and a symmetric neighbourhood T such that*

$$mT \subset r(A - A) \text{ and } m_G(T) \geq \exp(-O(s^2 r^3 \log^3 2K))m_G(A).$$

Proof. Define sequences

$$r_i := 3 \times 2^i - 2 \text{ and } K_i := \frac{m_G(r_i(A - A))}{m_G(A)};$$

by Plünnecke's inequality we have $K_i \leq K^{2^{r_i}}$.

We proceed inductively to define sequences of non-empty sets $(S_i)_{i \geq 0}$ and $(T_i)_{i \geq 0}$ with

$$L_i := \frac{m_G(S_i + T_i)}{m_G(S_i)} \text{ and } m_i := s \left\lceil \frac{\log 2K_{i+1}}{\sqrt{\log 2L_i}} \right\rceil.$$

We shall establish the following properties inductively for all $i \geq 0$.

(i) S_i and T_i are symmetric neighbourhoods of the identity such that

$$(A - A) \subset S_i \subset r_i(A - A);$$

(ii) and

$$L_i \leq \exp(4 \log^{2^{-i}} 2K);$$

(iii) and

$$m_i T_{i+1} \subset S_i + A - A - S_i;$$

(iv) and

$$m_G(T_{i+1}) \geq \exp \left(-O \left(s^2 \left(\sum_{j=0}^i r_{j+1}^3 \right) \log^3 2K \right) \right) m_G(T_0).$$

We initialise with $S_0 := A - A$ and $T_0 := A - A$ so that S_0 and T_0 are symmetric neighbourhoods of the identity (since A is non-empty) and

$$(A - A) = S_0 = A - A = 1(A - A) = r_0(A - A),$$

whence (i) holds. Moreover, by Plünnecke's inequality we have

$$L_0 = \frac{m_G(S_0 + T_0)}{m_G(S_0)} = \frac{m_G((A - A) + (A - A))}{m_G(A - A)} \leq K^4 \leq \exp(4 \log 2K),$$

so that (ii) holds.

Suppose that we are at stage i of the iteration. Apply Proposition 8.8 to the sets A , S_i , and T_i with parameter m_i . This produces a symmetric neighbourhood of the identity T_{i+1} such that

$$(8.4) \quad m_G(T_{i+1}) \geq \exp(-O(m_i^2 \log 2K_i \log 2L_i)) m_G(T_i) \text{ and } m_i T_{i+1} \subset S_i + A - A - S_i.$$

First note that given the definition of m_i , r_i and r_{i+1} we have

$$\begin{aligned} m_G(T_{i+1}) &\geq \exp(-O(s^2 \log^2 2K_{i+1} \log 2K_i)) m_G(T_i) \\ &= \exp(-O(s^2 r_{i+1}^3 \log^3 2K)) m_G(T_i), \end{aligned}$$

and so we get (iv). The second part of (8.4) ensures (iii). Moreover, we have

$$\begin{aligned} m_i T_{i+1} + (A - A) &\subset S_i + A - A - S_i + A - A \\ &\subset r_i(A - A) + (A - A) - r_i(A - A) + (A - A) \\ &= (2r_i + 2)(A - A) = r_{i+1}(A - A). \end{aligned}$$

By the pigeon-hole principle there is some non-negative integer $l_i \leq m_i/s - 1$ such that

$$(8.5) \quad \frac{m_G(sT_{i+1} + sl_i T_{i+1} + (A - A))}{m_G(sl_i T_{i+1} + (A - A))} \leq \frac{m_G(r_{i+1}(A - A))^{\frac{s}{m_i}}}{m_G(A - A)}.$$

Set $S_{i+1} := sl_i T_{i+1} + (A - A)$ which is a symmetric neighbourhood of the identity since both T_{i+1} and $A - A$ are. Since $0_G \in T_{i+1}$ and $l_i \leq m_i/s - 1$ we have

$$A - A \subset S_{i+1} \subset m_i T_{i+1} + (A - A) \subset r_{i+1}(A - A)$$

which gives (i). Moreover, from (8.5) we have

$$\begin{aligned}
L_{i+1} &= \frac{m_G(T_{i+1} + S_{i+1})}{m_G(S_{i+1})} \leq \frac{m_G(r_{i+1}(A - A))^{\frac{s}{m_i}}}{m_G(A - A)} \\
&\leq K_{i+1}^{\frac{s}{m_i}} \\
&\leq (2K_{i+1})^{\frac{s}{m_i}} \\
&\leq \exp(\sqrt{\log 2L_i}) \\
&\leq \exp(\sqrt{4 \log^{2^{-i}} 2K}) \leq \exp(4 \log 2^{-(i+1)} 2K),
\end{aligned}$$

so that (ii) holds.

Let $i \geq 1$ be maximal such that $2r_{i-1} + 1 \leq r$ (possible since $r \geq 3 = 2r_0 + 1$, so that

$$\sum_{j=0}^i r_j^3 = O(r^3) \text{ and } 2^{-i} = O(r^{-1}),$$

and put $T := T_i$. The result follows since

$$m_{i-1}T \subset S_{i-1} + A - A - S_{i-1} \subset (2r_{i-1} + 1)(A - A) \subset r(A - A),$$

and $m_G(T_0) \geq m_G(A)$. □

Proof of Lemma 8.2. Let $3 \leq r = O(\log 2 \log 2K)$ be such that $\log^{O(r^{-1})} 2K = O(1)$ and apply Proposition 8.9 to the set A with the parameter s to be optimised shortly. We get a natural $m = \Omega(rs \log 2K)$ and a symmetric neighbourhood of the identity X such that

$$mX \subset r(A - A) \text{ and } m_G(X) \geq \exp(-O(s^2 r^3 \log^3 2K)) m_G(A).$$

Let $k := m^3$. By Plünnecke's inequality we have

$$\begin{aligned}
m_G((3k + 1)X) &\leq m_G(3(m^2 + 1)mX) \\
&\leq m_G(3(m^2 + 1)r(A - A)) \\
&\leq K^{3m^2r} \exp(O(s^2 r^3 \log^3 2K)) m_G(X) \leq \exp(O(k/s)) m_G(X).
\end{aligned}$$

For $s = O(1)$ sufficiently large the right hand side is strictly less than 2^k (since X is non-empty) and hence we can apply Corollary 8.6 to see that X has relative polynomial growth of order $O((\log 2 \log 2K)^3 \log^3 2K)$. The result is proved. □

8.10. From relative polynomial growth to Bohr sets of bounded dimension. The next proposition is routine with the core of the argument coming from [GR07].

Lemma (Lemma 8.3). *Suppose that X is a symmetric non-empty set with relative polynomial growth of order $d \geq 1$. Then there is a Bohr system B with*

$$\dim B = O(d) \text{ and } m_G(B_1) = d^{O(d)} m_G(X),$$

such that $X - X \subset B_1$.

Proof. Let $m = O(d \log 2d)$ be a natural number such that $m^{\frac{d}{m-1}} \leq \frac{3}{2}$. Since X has relative polynomial growth of order d we see by the pigeonhole principle that there is some $2 \leq l \leq m$ such that

$$\frac{m_G(lX)}{m_G((l-1)X)} \leq \left(\frac{m_G(mX)}{m_G(X)} \right)^{\frac{1}{m-1}} \leq m^{\frac{d}{m-1}} \leq \frac{3}{2}.$$

Let $\epsilon := 1/2^{18}d^2$ (the reason for which choice will become clear later) and write

$$\Gamma := \{\gamma \in \widehat{G} : |\widehat{1_{lX}}(\gamma)| > (1 - \epsilon)m_G((l+1)X)\}$$

so that by Lemma 5.4 (applicable since $l \geq 2$) we have that

$$\Gamma \subset N(X - X, 2\sqrt{3\epsilon}).$$

Let $\delta : \Gamma \rightarrow \mathbb{R}_{>0}$ be the constant function taking the value 2^{-4} and B' be the Bohr system with frequency set Γ and width function δ . By the first part of Lemma 5.3 we see that

$$\begin{aligned} X - X &\subset \text{Bohr} \left(N(X - X, 2\sqrt{3\epsilon}), 1_{N(X-X, 2\sqrt{3\epsilon})} \frac{\epsilon}{2\sqrt{2}} \right) \\ (8.6) \quad &\subset \text{Bohr} \left(\Gamma, \sqrt{\frac{3\epsilon}{2}} \right) \subset B'_{1/2^{5d}}. \end{aligned}$$

We now show that this Bohr system is not too large. Let $k \in \mathbb{N}$ be a natural number to be optimised shortly. Begin by noting that

$$(8.7) \quad \int \left(1_{lX}^{(k)} \right)^2 dm_G \geq \frac{1}{m_G(k(lX))} \left(\int 1_{lX}^{(k)} dm_G \right)^2 \geq \frac{m_G(lX)^{2k-1}}{(kl)^d},$$

where $1_{lX}^{(k)}$ denotes the k -fold convolution of 1_{lX} with itself, and the inequalities are Cauchy-Schwarz and then the relative polynomial growth hypothesis. On the other hand, by Parseval's theorem

$$\begin{aligned} \sum_{\gamma \notin \Gamma} |\widehat{1_{lX}}(\gamma)|^{2k} &\leq ((1 - \epsilon)m_G(lX))^{2k-2} \sum_{\gamma \in \widehat{G}} |\widehat{1_{lX}}(\gamma)|^2 \\ &\leq \exp(-\Omega(kd^{-2})) m_G(lX)^{2k-1} \leq \frac{m_G(lX)^{2k-1}}{2(kl)^d} \end{aligned}$$

for some natural $k = O(d^3 \log d)$. In particular, from (8.7) we have that

$$\sum_{\gamma \notin \Gamma} |\widehat{1_{lX}}(\gamma)|^{2k} \leq \frac{1}{2} \int \left(1_{lX}^{(k)} \right)^2 dm_G.$$

It then follows from Parseval's theorem and the triangle inequality that

$$\begin{aligned} \sum_{\gamma \in \Gamma} |\widehat{1_{lX}}(\gamma)|^{2k} &= \sum_{\gamma \in \widehat{G}} |\widehat{1_{lX}}(\gamma)|^{2k} - \sum_{\gamma \notin \Gamma} |\widehat{1_{lX}}(\gamma)|^{2k} \\ &\geq \int \left(1_{lX}^{(k)} \right)^2 dm_G - \frac{1}{2} \int \left(1_{lX}^{(k)} \right)^2 dm_G = \frac{1}{2} \int \left(1_{lX}^{(k)} \right)^2 dm_G. \end{aligned}$$

Write β for the uniform probability measure induced on B'_1 . By the second part of Lemma 5.3 and the nesting of approximate annihilators we see that

$$\Gamma \subset N(B'_1, 2\pi\|\delta\|_{\ell_\infty(\Gamma)}) \subset N\left(B'_1, \frac{2\pi}{2^4}\right) \subset N\left(B'_1, \frac{1}{2}\right).$$

Thus by the triangle inequality, if $\gamma \in \Gamma$ then

$$|1 - \widehat{\beta}(\gamma)| = \left| \int (1 - \gamma(x)) d\beta(x) \right| \leq \int |1 - \gamma(x)| d\beta(x) \leq \frac{1}{2},$$

and hence $|\widehat{\beta}(\gamma)| \geq \frac{1}{2}$. We conclude that

$$\sum_{\gamma \in \widehat{G}} |\widehat{1_{lX}}(\gamma)|^{2k} |\widehat{\beta}(\gamma)|^2 \geq \frac{1}{4} \sum_{\gamma \in \Gamma} |\widehat{1_{lX}}(\gamma)|^{2k} \geq \frac{m_G(lX)^{2k-1}}{8(kl)^d}.$$

But, by Parseval's theorem and Hölder's inequality we have that

$$\begin{aligned} \sum_{\gamma \in \widehat{G}} |\widehat{1_{lX}}(\gamma)|^{2k} |\widehat{\beta}(\gamma)|^2 &= \int \left(1_{lX}^{(k)} * \beta\right)^2 dm_G \\ &= \int 1_{lX}^{(k)} * 1_{-lX}^{(k)} d\beta * \tilde{\beta} \\ &= m_G(B'_1)^{-1} \int 1_{lX}^{(k)} * 1_{-lX}^{(k)} 1_{B'_1} * \tilde{\beta} dm_G \\ &\leq m_G(B'_1)^{-1} \|1_{lX}^{(k)} * 1_{-lX}^{(k)}\|_{L_1(m_G)} \left\|1_{B'_1} * \tilde{\beta}\right\|_{L_\infty(G)} = \frac{m_G(lX)^{2k}}{m_G(B'_1)}, \end{aligned}$$

and so

$$(8.8) \quad m_G(B'_1) \leq 8(kl)^d m_G(lX) \leq \exp(O(d \log 2d)) m_G(X).$$

Now, note by sub-additivity and symmetry of Bohr sets and Ruzsa's Covering Lemma (Lemma 2.3) that for $i \geq 1$ we have

$$\begin{aligned} \mathcal{C}(B'_{2^{-i}}; B'_{2^{-(i+3)}}) &\leq \mathcal{C}(B'_{2^{-i}}; B'_{2^{-(i+4)}} - B'_{2^{-(i+4)}}) \leq \frac{m_G(B'_{2^{-i}} + B'_{2^{-(i+4)}})}{m_G(B'_{2^{-(i+4)}})} \\ &\leq \frac{m_G(B'_{2^{-(i-1)}})}{m_G(B'_{2^{-(i+4)}})}. \end{aligned}$$

Let $J := \left\lfloor \frac{\log_2 d}{5} \right\rfloor$ so that

$$\begin{aligned} \prod_{j=0}^J \mathcal{C}(B'_{2^{-(5j+1)}}; B'_{2^{-(5j+4)}}) &\leq \prod_{j=0}^J \frac{m_G(B'_{2^{-5j}})}{m_G(B'_{2^{-5(j+1)}})} \\ &\leq \frac{m_G(B'_1)}{m_G(B'_{2^{-5(J+1)}})} \leq \frac{m_G(B'_1)}{m_G(B'_{1/2^{5d}})} \leq \frac{m_G(B'_1)}{m_G(X-X)}, \end{aligned}$$

where the last inequality is from (8.6).

By averaging there is some $0 \leq j \leq J$ such that

$$\mathcal{C}(B'_{2^{-(5j+1)}}; B'_{2^{-(5j+4)}}) \leq \left(\frac{m_G(B'_1)}{m_G(X - X)} \right)^{\frac{1}{J}} = \exp(O(d)),$$

where the last inequality is from (8.8).

Set $B := 2^{-(5j+1)}B'$ and apply Lemma 3.4 (possible since $w(B) \leq 2^{-5} < \frac{1}{4}$) to see that $\dim^* B = O(d)$. It follows by the second inequality in Lemma 3.7 part (iii) that $\dim B = O(d)$. Moreover, nesting of Bohr sets tells us that $X - X \subset B_1$ and

$$m_G(B_1) \leq m_G(B'_1) \leq \exp(O(d \log 2d)).$$

The result is proved. \square

8.11. Bogoliùboff-Chang. In the paper [Bog39] Bogoliùboff showed how to find Bohr sets inside four-fold sumsets. The importance of this was emphasised by Ruzsa in [Ruz94] and refined by Chang in [Cha02]. We shall need the following result in our work.

Lemma (Lemma 8.4). *Suppose that A is a non-empty set, B is a Bohr system and μ is a B -approximately invariant probability measure, $S \subset B_1$ has $\mu(S) > 0$, and L , non-empty, is such that $\|1_L * \mu_S\|_{L_2(m_G)}^2 \geq \epsilon m_G(L)$. Then there is a Bohr system $B' \leq B$ with*

$$\mathcal{C}^\Delta(A; B'_1) \leq (2\epsilon^{-1})^{O(\epsilon^{-2} \log 2\mu(S)^{-1})} \mathcal{C}^\Delta(A; B_1)$$

and

$$\dim B' = \dim B + O(\epsilon^{-2} \log 2\mu(S)^{-1})$$

such that $B'_1 \subset L - L + S - S$.

Proof. Since μ is B -approximately invariant and $\tilde{\mu}$ is a probability measure, Lemma 4.3 tells us that $\mu * \tilde{\mu}$ is B -approximately invariant. By Parseval's theorem we have

$$\|1_L * 1_{-L}\|_{A(G)} = \sum_{\gamma \in \hat{G}} |\widehat{1_L}(\gamma)|^2 = \int 1_L^2 dm_G = m_G(L).$$

Apply Lemma 6.2 to B , $\mu * \tilde{\mu}$, and $1_L * 1_{-L}$ with parameters $p \geq 2$ and $\eta \in (0, 1]$ to be optimised later. This gives us a Bohr system B' with

$$\mathcal{C}^\Delta(A; B'_1) \leq (2\eta^{-1})^{O(p\eta^{-2})} \mathcal{C}^\Delta(A; B_1) \text{ and } \dim B' \leq \dim B + O(p\eta^{-2})$$

such that

$$\|\tau_x(1_L * 1_{-L}) - 1_L * 1_{-L}\|_{L_p(\mu * \tilde{\mu})} \leq \eta m_G(L) \text{ for all } x \in B'_1.$$

Since μ is non-negative we have

$$0 \leq \mu_S * \tilde{\mu}_S \leq \mu(S)^{-2} \mu * \tilde{\mu},$$

and so there is a function f with $0 \leq f \leq \mu(S)^{-2}$ point-wise such that

$$\int g d\mu_S * \tilde{\mu}_S = \int g f d\mu * \tilde{\mu} \text{ for all } g \in L_1(\mu_S * \tilde{\mu}_S).$$

(f is the Radon-Nikodym derivative of $\mu_S * \tilde{\mu}_S$ with respect to $\mu * \tilde{\mu}$.)

Write p' for the conjugate index of p (so $\frac{1}{p} + \frac{1}{p'} = 1$) we have

$$\|f\|_{L_{p'}(\mu * \tilde{\mu})} \leq \left(\int \mu(S)^{-2(p'-1)} f d\mu * \tilde{\mu} \right)^{1/p'} = \mu(S)^{-2/p}.$$

If we take $p = 2 + 2 \log \mu(S)^{-1}$ then we see from Hölder's inequality that for all $x \in B'_1$ we have

$$\begin{aligned} & |\langle 1_L * 1_{-L}, \mu_S * \widetilde{\mu_S} \rangle - \langle \tau_x(1_L * 1_{-L}), \mu_S * \widetilde{\mu_S} \rangle| \\ &= |\langle 1_L * 1_{-L}, f \rangle_{L_2(\mu * \tilde{\mu})} - \langle \tau_x(1_L * 1_{-L}), f \rangle_{L_2(\mu * \tilde{\mu})}| \\ &= |\langle 1_L * 1_{-L} - \tau_x(1_L * 1_{-L}), f \rangle_{L_2(\mu * \tilde{\mu})}| \\ &\leq \|1_L * 1_{-L} - \tau_x(1_L * 1_{-L})\|_{L_p(\mu * \tilde{\mu})} \|f\|_{L_{p'}(\mu * \tilde{\mu})} \leq e\eta m_G(L). \end{aligned}$$

By hypothesis

$$\langle 1_L * 1_{-L}, \mu_S * \widetilde{\mu_S} \rangle = \|1_L * \mu_S\|_{L_2(m_G)}^2 \geq \epsilon m_G(L);$$

it follows that for $\eta = \frac{1}{2e}\epsilon$ we have

$$\langle \tau_x(1_L * 1_{-L}), \mu_S * \widetilde{\mu_S} \rangle \geq \frac{\epsilon}{2} m_G(L) \text{ for all } x \in B'_1.$$

However, the left hand side is 0 if $x + L - L \cap S - S = \emptyset$ i.e. if $x \notin L - L + S - S$. The result is proved. \square

9. ARITHMETIC CONNECTIVITY

The basic approach of our main argument (captured in Lemma 10.2) is iterative and to make this work we need to consider not just integer-valued functions, but *almost* integer-valued functions. For $\epsilon \in (0, 1/2)$ we say that $f : G \rightarrow \mathbb{C}$ is ϵ -**almost integer-valued** if there is a function $f_{\mathbb{Z}} : G \rightarrow \mathbb{Z}$ such that

$$\|f - f_{\mathbb{Z}}\|_{L_{\infty}(G)} \leq \epsilon.$$

Since $\epsilon < 1/2$ this actually means that $f_{\mathbb{Z}}$ is uniquely defined.

When a function f has small algebra norm and is close to integer-valued, it turns out that $f_{\mathbb{Z}}$ has a lot of additive structure. This is captured by a concept called arithmetic connectivity identified by Green in [GS08, Definition 6.4]. We shall need a slight refinement of this: for $m, l \in \mathbb{N}$ we say that a set A is (m, l) -**arithmetically connected** if for every $x \in A^m$ there is some $\sigma \in \mathbb{Z}^m$ with $\|\sigma\|_{\ell_1^m} \leq l$ and $|\sigma_i| = 1$ for at least two i such that

$$\sigma \cdot x := \sum_i \sigma_i x_i \in A.$$

The definition is perhaps a little odd. To help we present some simple examples we leave as exercises.

- (i) A is $(m, 1)$ -arithmetically connected for some m if and only if $A = \emptyset$.
- (ii) if every element of A has order 2 then A is $(m, m+k)$ -arithmetically connected for some $k \geq 0$ if and only if it is (m, m) arithmetically connected.

- (iii) if A is a subgroup then $x + y \in A$ for all $x, y \in A$ and so A is $(2, 2)$ -arithmetically connected. Conversely, if A is $(2, 2)$ -arithmetically connected then $x + y \in A$ for all $x, y \in A$. Since we are taking G to be finite it follows that A is a subgroup. However, nothing about the definition of arithmetic connectivity requires G to be finite and in, for example, \mathbb{Z} there are sets such as \mathbb{N} that are $(2, 2)$ -arithmetically connected but are not ‘close’ to any subgroup.
- (iv) If A is a coset of a subgroup then for any $x, y, z \in A$ we have $x + y - z \in A$ and so A is $(3, 3)$ -arithmetically connected.

Arithmetic connectivity is related to additive structure by the following easy adaptation of [GS08, Proposition 6.5].

Lemma 9.1. *Suppose that A is (m, l) -arithmetically connected. Then*

$$\|1_A * 1_A\|_{L_2(m_G)}^2 = m^{-O(l)} m_G(A)^3.$$

Proof. First we count the number of $\sigma \in \mathbb{Z}^m$ such that $\|\sigma\|_{\ell_1^m} \leq l$. The number of ways of writing a total of r as a sum of m non-negative integers is $\binom{r+m}{m}$. For each such σ we can choose the signs of the various integers in at most 2^l ways (since at most l of them are non-zero) and so the total number of $\sigma \in \mathbb{Z}^m$ with $\|\sigma\|_{\ell_1^m} \leq l$ is at most

$$\sum_{r=0}^l \binom{r+m}{m} 2^l = m^{O(l)}.$$

It follows that there is such a $\sigma \in \mathbb{Z}^m$ such that for at least $m^{-O(l)}$ vectors $x \in A^m$ we have $\sigma \cdot x \in A$. Rewriting this we have

$$\begin{aligned} m_G(A)^m m^{-O(l)} &\leq \int 1_A \left(\sum_{i=1}^m \sigma_i x_i \right) \prod_{i=1}^m 1_A(x_i) dm_G(x_i) \\ &= \sum_{\gamma} \widehat{1_A}(\gamma) \prod_{i=1}^m \widehat{1_A}(-\sigma_i \cdot \gamma). \end{aligned}$$

Since $|\sigma_i| = 1$ for at least two $i \in [m]$, $|\widehat{1_A}(\gamma)| = |\widehat{1_A}(-\gamma)|$, and $|\widehat{1_A}(-\sigma_i \cdot \gamma)| \leq m_G(A)$ by the Hausdorff-Young inequality we conclude that

$$m_G(A)^{m-2} \sum_{\gamma} |\widehat{1_A}(\gamma)|^3 \geq m_G(A)^m m^{-O(l)}.$$

The result now follows from Cauchy-Schwarz and Parseval’s theorem which gives

$$\sum_{\gamma} |\widehat{1_A}(\gamma)|^3 \leq \left(\sum_{\gamma} |\widehat{1_A}(\gamma)|^4 \right)^{1/2} \left(\sum_{\gamma} |\widehat{1_A}(\gamma)|^2 \right)^{1/2} = \left(\sum_{\gamma} |\widehat{1_A}(\gamma)|^4 \right)^{1/2} m_G(A)^{1/2}.$$

□

On the other hand additive connectivity is related to small algebra norm via the following result.

Proposition 9.2. *There is an absolute constant $C_{\text{MÉL}} > 0$ such that the following holds. Suppose that $g \in A(G)$ is ϵ -almost integer-valued for some $\epsilon \in (0, 1/2)$ and has $\|g\|_{A(G)} \leq M$ for some $M \geq 1$. Then provided $\epsilon \leq \exp(-C_{\text{MÉL}}M)$, the set $\text{supp } g_{\mathbb{Z}}$ is $(O(M^3), O(M))$ -arithmetically connected.*

The proof of this owes a lot to [Mél82, Lemma 1] of Méla, and we are grateful to Ben Green for directing us to that paper. Indeed, as noted in [GS08, §9] an example in Méla's paper shows that one cannot hope to weaken the requirement that $\epsilon \leq \exp(-CM)$ to anything with C below a certain absolute threshold.

We write $T_n(x)$ for the Chebyshev polynomial of degree n . Recall (from, for example, [ZKR03, §6.10.6]) that we have a formula for T_n :

$$T_n(x) = \frac{n}{2} \sum_{r=0}^{\lfloor n/2 \rfloor} \frac{(-1)^r}{n-r} \binom{n-r}{r} (2x)^{n-2r} = \cos(n \arccos x);$$

the last form tells us immediately that $\|T_n\|_{L_\infty([-1,1])} \leq 1$.

We shall be particularly interested in the Chebyshev polynomials of odd degree. Indeed, note from the above formula that if $n = 2l + 1$ for some non-negative integer l , then only the coefficients of odd powers of x are non-zero and

$$T_{2l+1}(x) = \sum_{j=0}^l c(j, l) x^{2j+1},$$

where

$$c(j, l) = 2^{2j} (-1)^{l-j} \frac{2l+1}{2j+1} \binom{l+j}{l-j} = 2^{2j} (-1)^{l-j} \frac{2l+1}{2j+1} \binom{l+j}{2j}.$$

In view of this we have

$$(9.1) \quad |c(0, l)| = 2l+1 \text{ and } |c(j, l)| = O(l/j)^{2j+1}.$$

Added to this information we shall need the following lemma.

Lemma 9.3. *Suppose that $m \in \mathbb{N}$, and $l \in \mathbb{N}_0$ are parameters, $g : G \rightarrow \mathbb{C}$ has support A and $x \in G^m$ is such that if $\sigma \in \mathbb{Z}^m$ has $\|\sigma\|_{\ell_1^m} \leq 2l+1$ and $\sigma \cdot x \in A$ then $|\sigma_i| = 1$ for at most one value of i . Then for every $\omega \in \ell_\infty^m$ with $\|\omega\|_{\ell_\infty^m} \leq 1$ and $0 \leq r \leq l$ we have*

$$\left| \sum_{\gamma} \left(\text{Re} \sum_{i=1}^m \omega_i \gamma(x_i) \right)^{2r+1} \overline{\widehat{g}(\gamma)} \right| = \exp(O(r+1)) (r+1)^r m^{r+1} \|g\|_{L_\infty(G)}.$$

Proof. We write \mathcal{C} for the conjugation operator and note that by Fourier inversion we have

$$\begin{aligned}
& \sum_{\gamma} \left(\operatorname{Re} \sum_{i=1}^m \omega_i \gamma(x_i) \right)^{2r+1} \mathcal{C}(\widehat{g}(\gamma)) \\
&= \sum_{\gamma} \left(\sum_{i=1}^m \frac{1}{2} (\omega_i \gamma(x_i) + \mathcal{C}(\omega_i) \gamma(-x_i)) \right)^{2r+1} \mathcal{C}(\widehat{g}(\gamma)) \\
&= \frac{1}{2^{2r+1}} \sum_{\substack{\pi: [2r+1] \rightarrow [m] \\ \iota: [2r+1] \rightarrow \{0,1\}}} \sum_{\gamma} \mathcal{C}(\widehat{g})(\gamma) \gamma \left(\sum_{i=1}^{2r+1} (-1)^{\iota_i} x_{\pi_i} \right) \prod_{i=1}^{2r+1} \mathcal{C}^{\iota_i}(\omega_{\pi_i}) \\
&= \frac{1}{2^{2r+1}} \sum_{\substack{\pi: [2r+1] \rightarrow [m] \\ \iota: [2r+1] \rightarrow \{0,1\}}} \mathcal{C}(g) \left(- \sum_{i=1}^{2r+1} (-1)^{\iota_i} x_{\pi_i} \right) \prod_{i=1}^{2r+1} \mathcal{C}^{\iota_i}(\omega_{\pi_i}).
\end{aligned}$$

Applying the triangle inequality we see that

$$(9.2) \quad \left| \sum_{\gamma} \left(\operatorname{Re} \sum_{i=1}^m \omega_i \gamma(x_i) \right)^{2r+1} \overline{\widehat{g}(\gamma)} \right| \leq \frac{1}{2^{2r+1}} \sum_{\substack{\pi: [2r+1] \rightarrow [m] \\ \iota: [2r+1] \rightarrow \{0,1\}}} \|g\|_{L_{\infty}(G)} 1_A \left(- \sum_i (-1)^{\iota_i} x_{\pi_i} \right).$$

Given $\pi : [2r+1] \rightarrow [m]$ and $\iota : [2r+1] \rightarrow \{0,1\}$ we define $\sigma(\pi, \iota) \in \mathbb{Z}^m$ by

$$\sigma_j(\pi, \iota) := - \sum_{i: \pi_i = j} (-1)^{\iota_i}.$$

By the triangle inequality we have

$$\|\sigma(\pi, \iota)\|_{\ell_1^m} = \sum_{j=1}^m |\sigma_j| \leq \sum_{j=1}^m \sum_{i: \pi_i = j} 1 = 2r+1 \leq 2l+1.$$

Moreover,

$$\sigma(\pi, \iota) \cdot x = \sum_{j=1}^m \sigma_j(\pi, \iota) x_j = - \sum_{j=1}^m x_j \sum_{i: \pi_i = j} (-1)^{\iota_i} = - \sum_{i=1}^{2r+1} (-1)^{\iota_i} x_{\pi_i},$$

and so $1_A(\sigma(\pi, \iota) \cdot x) = 0$ unless $|\sigma_j(\pi, \iota)| = 1$ for at most one $j \in [m]$. It remains to bound from above the number of functions $\pi : [2r+1] \rightarrow [m]$ and $\iota : [2r+1] \rightarrow \{0,1\}$ such that $|\sigma_j(\pi, \iota)| = 1$ for at most one $j \in [m]$. Since $|\sigma_j(\pi, \iota)| = 1$ for at most one j it follows that the image of π has size at most $r+1$, and hence the number of pairs (π, ι) is at most

$$\binom{m}{r+1} \cdot (r+1)^{2r+1} \cdot 2^{2r+1} = \exp(O(r+1))(r+1)^r m^{r+1}.$$

Inserting this into (9.2) gives the result. \square

Proof of Proposition 9.2. Let $A := \text{supp } g_{\mathbb{Z}}$, and take l and m to be parameters to be chosen later. Suppose that A is not $(m, 2l + 1)$ -arithmetically connected, so that there is some $x \in A^m$ such that for all $\sigma \in \mathbb{Z}^m$ with $\|\sigma\|_{\ell_1^m} \leq 2l + 1$ and $|\sigma_i| = 1$ for at least two $i \in [m]$, we have $g_{\mathbb{Z}}(\sigma \cdot x) = 0$.

Our first task is to define $\omega \in \ell_{\infty}^m$. With ω appropriately defined we shall put

$$h := \frac{|G|}{m} \sum_{j=1}^m \frac{1}{2} (\omega_j 1_{\{x_j\}} + \overline{\omega_j} 1_{\{-x_j\}}),$$

so that

$$\|h\|_{L_1(m_G)} \leq 1 \text{ and } \widehat{h}(\gamma) = \frac{1}{m} \text{Re} \sum_{j=1}^m \omega_j \gamma(x_j).$$

The function $g_{\mathbb{Z}}$ is real and since $x_j \in A$ we see that $|g_{\mathbb{Z}}(x_j)| \geq 1$ for all $j \in [m]$. It follows that either

- (i) either at least $1/3$ of the indices $j \in [m]$ have $g_{\mathbb{Z}}(-x_j) = 0$, in which case we set $\omega_j = \text{sgn } g_{\mathbb{Z}}(x_j)$ for all these indices and $\omega_j = 0$ for all others, and get

$$\sum_{j=1}^m \frac{1}{2} (\omega_j g_{\mathbb{Z}}(x_j) + \overline{\omega_j} g_{\mathbb{Z}}(-x_j)) \geq \frac{m}{6};$$

- (ii) or at least $1/3$ of the indices $j \in [m]$ have $\text{sgn } g_{\mathbb{Z}}(x_j) = \text{sgn } g_{\mathbb{Z}}(-x_j)$, in which case we set $\omega_j = \text{sgn } g_{\mathbb{Z}}(x_j)$ for all these indices and $\omega_j = 0$ for all others and get

$$\sum_{j=1}^m \frac{1}{2} (\omega_j g_{\mathbb{Z}}(x_j) + \overline{\omega_j} g_{\mathbb{Z}}(-x_j)) \geq \frac{m}{3};$$

- (iii) or at least $1/3$ of the indices $j \in [m]$ have $\text{sgn } g_{\mathbb{Z}}(x_j) = -\text{sgn } g_{\mathbb{Z}}(-x_j)$, in which case we set $\omega_j = i$ for all these indices and $\omega_j = 0$ for all others and get

$$\left| \sum_{j=1}^m \frac{1}{2} (\omega_j g_{\mathbb{Z}}(x_j) + \overline{\omega_j} g_{\mathbb{Z}}(-x_j)) \right| = \left| \sum_{j=1}^m \frac{1}{2} (g_{\mathbb{Z}}(x_j) - g_{\mathbb{Z}}(-x_j)) \right| \geq \frac{m}{3}.$$

By construction $\|\omega\|_{\ell_{\infty}^m} \leq 1$ and

$$\left| \left\langle \widehat{h}, \widehat{g_{\mathbb{Z}}} \right\rangle_{\ell_2(\widehat{G})} \right| = \left| \sum_{j=1}^m \frac{1}{2} (\omega_j g_{\mathbb{Z}}(x_j) + \overline{\omega_j} g_{\mathbb{Z}}(-x_j)) \right| \geq \frac{1}{6}.$$

By Lemma 9.3 for every $1 \leq r \leq l$ we have

$$\begin{aligned} \left| \left\langle \widehat{h}^{2r+1}, \widehat{g_{\mathbb{Z}}} \right\rangle_{\ell_2(\widehat{G})} \right| &= \left| \sum_{\gamma} \left(\text{Re} \sum_{i=1}^m \omega_i \gamma(x_i) \right)^{2r+1} \overline{\widehat{g_{\mathbb{Z}}}(\gamma)} \right| \\ &= \exp(O(r+1)) (r+1)^r m^{r+1} \|g_{\mathbb{Z}}\|_{L_{\infty}(G)} \\ &= O(r)^r m^{r+1} (\|g\|_{L_{\infty}(G)} + \epsilon) = O(r)^r m^{r+1} M. \end{aligned}$$

On the other hand, by Young's inequality $\|h^{(2r+1)}\|_{L_1(m_G)} \leq 1$ and so by Plancherel's theorem we see that

$$\begin{aligned} \left| \langle \widehat{h}^{2r+1}, \widehat{g_{\mathbb{Z}}} \rangle_{\ell_2(\widehat{G})} - \langle \widehat{h}^{2r+1}, \widehat{g} \rangle_{\ell_2(\widehat{G})} \right| &= \left| \langle (h^{(2r+1)})^\wedge, \widehat{g_{\mathbb{Z}}} \rangle_{\ell_2(\widehat{G})} - \langle (h^{(2r+1)})^\wedge, \widehat{g} \rangle_{\ell_2(\widehat{G})} \right| \\ &= \left| \langle (h^{(2r+1)})^\wedge, (g_{\mathbb{Z}} - g)^\wedge \rangle_{\ell_2(\widehat{G})} \right| \\ &= \left| \langle h^{(2r+1)}, g_{\mathbb{Z}} - g \rangle_{L_2(m_G)} \right| \leq \|g - g_{\mathbb{Z}}\|_{L_\infty(G)} \leq \epsilon \end{aligned}$$

for all $0 \leq r \leq l$.

Finally, $-1 \leq \widehat{h}(\gamma) \leq 1$, and so $|T_{2l+1}(\widehat{h})| \leq 1$ and hence by (9.1) we get

$$\begin{aligned} M &\geq \left| \langle T_{2l+1}(\widehat{h}), \widehat{g} \rangle_{\ell_2(\widehat{G})} \right| \\ &\geq \left| \sum_{r=0}^l c(r, l) \langle \widehat{h}^{2r+1}, \widehat{g} \rangle_{\ell_2(\widehat{G})} \right| \\ &\geq |c(0, l)| |\langle \widehat{h}, \widehat{g} \rangle_{\ell_2(\widehat{G})}| - \sum_{r=1}^l |c(r, l)| |\langle \widehat{h}^{2r+1}, \widehat{g} \rangle_{\ell_2(\widehat{G})}| \\ &\geq |c(0, l)| |\langle \widehat{h}, \widehat{g_{\mathbb{Z}}} \rangle_{\ell_2(\widehat{G})}| - \epsilon \sum_{r=0}^l |c(r, l)| - \sum_{r=0}^l |c(r, l)| |\langle \widehat{h}^{2r+1}, \widehat{g_{\mathbb{Z}}} \rangle_{\ell_2(\widehat{G})}| \\ &\geq (2l+1) \frac{1}{6} - \epsilon \sum_{r=1}^l O\left(\frac{l}{r}\right)^{2r+1} - M \sum_{r=1}^l O\left(\frac{l}{r}\right)^{2r+1} O(r)^r m^{-r} \\ &\geq \frac{l}{3} - \epsilon \exp(O(l)) - M \frac{l^3}{m} \exp(O(l^2/m)). \end{aligned}$$

It follows that if $\epsilon \leq \exp(C_1 l)$ for some sufficiently large $C_1 > 0$, $m = C_2 l^3$ for some sufficiently large $C_2 > 0$ and $l = C_3 M$ for some sufficiently large $C_3 > 0$ then we arrive at a contradiction, and we find that A is $(m, 2l+1)$ -arithmetically connected. \square

10. THE MAIN ARGUMENT

We shall prove the following theorem of which Theorem 1.1 is a special case.

Theorem 10.1. *There is an absolute constant $C'_{\text{MÉL}} > 0$ such that if $M \geq 1$ and $\epsilon \in [0, 1]$ are such that $\epsilon \leq \exp(-C'_{\text{MÉL}} M)$, and $f : G \rightarrow \mathbb{Z}$ is ϵ -almost integer-valued with $\|f\|_{A(G)} \leq M$, then there is some $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ such that*

$$f_{\mathbb{Z}} = \sum_{W \in \mathcal{W}(G)} z(W) 1_W \text{ and } \|z\|_{\ell_1(\mathcal{W}(G))} \leq \exp(O(M^4 \log^8 2M)).$$

To do this we combine all our previous work into our key iterative lemma.

Lemma 10.2. *Suppose that $f \in A(G)$ is ϵ -almost integer-valued, $\|f\|_{A(G)} \leq M$ for some $M \geq 1$, $\text{supp } f_{\mathbb{Z}}$ is non-empty and $\eta \in (0, 1]$ a parameter. Then provided we have*

$\epsilon \leq \min\{\exp(-C_{\text{MÉL}}M), 1/8\}$ there is a function g that is $(\epsilon + \eta)$ -almost integer-valued, a subgroup $H \leq G$, and a function $z : G/H \rightarrow \mathbb{Z}$ with

$$\|z\|_{\ell_1(G/H)} \leq \exp(O(M^4 \log^8 2M + M^3 \log \eta^{-1}(\log 2 \log 2\eta^{-1}))),$$

such that

$$g_{\mathbb{Z}} = \sum_{W \in G/H} z(W)1_W \text{ and } \|f - g\|_{A(G)} \leq 1 - (\epsilon + \eta).$$

Proof. Apply Proposition 9.2 to f to get that the set $A := \text{supp } f_{\mathbb{Z}}$ is $(O(M^3), O(M))$ -arithmetically connected (provided ϵ is sufficiently small). By Lemma 9.1 we see that

$$\|1_A * 1_A\|_{L_2(m_G)}^2 = \exp(-O(M \log 2M))m_G(A)^3.$$

It follows from the Balog-Szemerédi-Gowers Theorem that there is a set $A' \subset A$ such that

$$m_G(A') = \exp(-O(M \log 2M))m_G(A) \text{ and } m_G(A' + A') \leq \exp(O(M \log 2M))m_G(A').$$

By Proposition 8.1 there is a Bohr system B with

$$\dim B = O(M^3 \log^7 2M) \text{ and } \mathcal{C}^\Delta(A'; B_1) = \exp(O(M^3 \log^7 2M))$$

and a constant $\psi = \exp(-O(M \log^2 2M))$ such that

$$(10.1) \quad \|1_{A'} * \beta\|_{L_\infty(G)} \geq \psi \text{ for all probability measures } \beta \text{ with } \text{supp } \beta \subset B_1.$$

Apply Proposition 7.1 to the set A' , the Bohr system B , $d := 1 + \dim B$, and the function f with parameters

$$\delta := 1/2^4 M \text{ and } \kappa := 1/2^5 M,$$

and

$$\begin{aligned} p &:= \max\{100C_{\text{MÉL}}M, 1 + \log_2 \psi^{-1}, 3 + \log_3 M + \log_3 \eta^{-1}\} \\ &= O(\max\{M \log^2 2M, \log \eta^{-1}\}) \end{aligned}$$

to get a Bohr system $B' \leq B$ with

$$\begin{aligned} \mathcal{C}^\Delta(A'; B'_1) &\leq \exp(O(\delta^{-1}d \log 2\kappa^{-1}d + p\delta^{-3} \log^3 2p\kappa^{-1}\delta^{-1}))\mathcal{C}^\Delta(A'; B_1) \\ &\leq \exp(O(M^4 \log^8 2M + M^3 \log \eta^{-1}(\log 2 \log 2\eta^{-1}))) \end{aligned}$$

and

$$\dim B' \leq d + O(p\delta^{-2} \log^2 2\delta^{-1}) = O(M^3 \log^7 2M + M^2(\log^2 2M) \log \eta^{-1}),$$

and a B' -approximately invariant probability measure μ and a probability measure ν supported on B'_κ such that

$$\sup_{x \in G} \|f - f * \mu\|_{L_p(\tau_x(\nu))} \leq \delta M.$$

By the integral triangle inequality it follows that

$$\sup_{x \in G} \|f - f * \mu\|_{L_p(\tau_x(\nu * \tilde{\nu}))} \leq \delta M.$$

Since μ is B' -approximately invariant and $\kappa \leq 1/2$ it follows from Lemma 4.2 that for all $y \in \text{supp } \nu * \tilde{\nu}$ we have

$$|f * \mu(y + x) - f * \mu(x)| \leq 2\kappa \|f\|_{L_\infty(G)} \leq 2\kappa M,$$

and hence

$$\sup_{x \in G} \|f - f * \mu(x)\|_{L_p(\tau_x(\nu * \tilde{\nu}))} \leq \delta M + 2\kappa M = (\delta + 2\kappa)M.$$

By the triangle inequality we then have

$$(10.2) \quad \sup_{x \in G} \|f_{\mathbb{Z}} - f * \mu(x)\|_{L_p(\tau_x(\nu * \tilde{\nu}))} \leq (\delta + 2\kappa)M + \epsilon \leq \frac{1}{4},$$

given the choices of δ and κ , and the upper bound on ϵ . We put $k := (f * \mu)_{\mathbb{Z}}$ which will turn out to be the $g_{\mathbb{Z}}$ in the conclusion. We establish the various properties in order.

Claim. $f * \mu$ is $\frac{1}{4}$ -almost integer-valued i.e. $\|k - f * \mu\|_{L_{\infty}(G)} \leq \frac{1}{4}$.

Proof. Suppose that there is some $x \in G$ such that $|f * \mu(x) - k(x)| > \frac{1}{4}$. Then

$$\begin{aligned} \|f_{\mathbb{Z}} - f * \mu(x)\|_{L_p(\tau_x(\nu * \tilde{\nu}))} &\geq \|(f * \mu)_{\mathbb{Z}} - f * \mu(x)\|_{L_p(\tau_x(\nu * \tilde{\nu}))} \\ &\geq \|(f * \mu)_{\mathbb{Z}} - f * \mu(x)\|_{L_p(\tau_x(\nu * \tilde{\nu}))} > \frac{1}{4} \end{aligned}$$

which contradicts (10.2). \square

Claim. k is invariant under translation by elements of B'_{κ} .

Proof. Since μ is B' -approximately invariant it follows by the triangle inequality and Lemma 4.2 that for all $y \in B'_{\kappa}$ and $x \in G$ we have

$$\begin{aligned} |k(y + x) - k(x)| &\leq |k(y + x) - f * \mu(y + x)| \\ &\quad + |f * \mu(y + x) - f * \mu(x)| + |f * \mu(x) - k(x)| \\ &\leq \frac{1}{2} + 2M\kappa < 1. \end{aligned}$$

It follows that $k(y + x) = k(x)$ as claimed. \square

The next two claims require the same calculation. Put $\theta_x := \tau_x(\nu * \tilde{\nu})(\{y : f_{\mathbb{Z}}(y) \neq k(x)\})$ and note that

$$\begin{aligned} \|f_{\mathbb{Z}} - f * \mu(x)\|_{L_p(\tau_x(\nu * \tilde{\nu}))}^p &\geq \int_{\{z : f_{\mathbb{Z}}(z) \neq k(x)\}} |f_{\mathbb{Z}}(y) - k(x)| - |k(x) - f * \mu(x)|^p d\tau_x(\nu * \tilde{\nu})(y) \\ &\geq \theta_x \left(\frac{3}{4}\right)^p. \end{aligned}$$

In light of (10.2) we then have $\theta_x \leq 3^{-p}$.

Claim. $\|f * \nu * \tilde{\nu} - k\|_{L_{\infty}(G)} \leq \eta + \epsilon$ so that $f * \nu * \tilde{\nu}$ is $(\epsilon + \eta)$ -almost integer-valued and $(f * \nu * \tilde{\nu})_{\mathbb{Z}} = k$.

Proof. By the triangle inequality we see that

$$\begin{aligned} |f * \nu * \tilde{\nu}(x) - k(x)| &\leq |f_{\mathbb{Z}} * \nu * \tilde{\nu}(x) - k(x)| + |(f - f_{\mathbb{Z}}) * \nu * \tilde{\nu}(x)| \\ &\leq \theta_x \|f_{\mathbb{Z}}\|_{L_{\infty}(G)} + \epsilon \leq (M + \epsilon)\theta_x + \epsilon \leq 2M3^{-p} + \epsilon. \end{aligned}$$

It follows that $f * \nu * \tilde{\nu}$ is $(\eta + \epsilon)$ -almost integer-valued in light of the choice of p . Since $2M3^{-p} + \epsilon < \frac{1}{2}$ we see that the integer part is unique and so $(f * \nu * \tilde{\nu})_{\mathbb{Z}} = k$. \square

Claim. $k \not\equiv 0$.

Proof. Since $\kappa \leq 1/2$ and $B' \leq B$ we see that $\text{supp } \nu * \tilde{\nu} \subset B_1$, and hence by (10.1) that

$$1_{A'} * \nu * \tilde{\nu}(x) \geq \psi$$

for some $x \in G$. If $k(x) = 0$ then

$$\psi \leq 1_{A'} * \nu * \tilde{\nu}(x) \leq 1_A * \nu * \tilde{\nu}(x) = \tau_x(\nu * \tilde{\nu})(\{y : f_{\mathbb{Z}}(y) \neq 0\}) = \theta_x \leq 3^{-p},$$

which contradicts the choice of p . It follows that $k(x) \neq 0$. \square

Claim. $\|k\|_{L_1(m_G)} \leq 2Mm_G(\text{supp } f_{\mathbb{Z}})$.

Proof. Note that

$$|k(x)| - \|(f_{\mathbb{Z}} - f) * \mu\|_{L_{\infty}(G)} - \|f * \mu - k\|_{L_{\infty}(G)} \leq |f_{\mathbb{Z}} * \mu(x)|,$$

and so

$$\frac{1}{2} \int |k(x)| dm_G(x) \leq \int |f_{\mathbb{Z}} * \mu(x)| dm_G(x) \leq (M + \epsilon)m_G(\text{supp } f_{\mathbb{Z}}).$$

\square

Write H for the group generated by B'_{κ} so that Lemma 2.2, Lemma 2.4 part (iv), and Lemma 3.8 part (i) tell us

$$\begin{aligned} m_G(H) &\geq m_G(B'_{\kappa}) \geq \frac{m_G(A')}{\mathcal{C}(A'; B'_{\kappa})} \geq \frac{m_G(A')}{\mathcal{C}^{\Delta}(A'; B'_{\kappa})} \geq \left(\frac{\kappa}{4}\right)^{\dim B'} \frac{m_G(A')}{\mathcal{C}^{\Delta}(A'; B'_1)} \\ &\geq \exp(-O(M^4 \log^8 2M + M^3 \log \eta^{-1}(\log 2 \log 2\eta^{-1})))m_G(\text{supp } f_{\mathbb{Z}}). \end{aligned}$$

From the claims, k is H -invariant and so there is a well-defined function $z : G/H \rightarrow \mathbb{Z}$ such that $z(W) = k(w)$ for all $w \in W$. Now we have from the claims that

$$\|z\|_{\ell_1(G/H)} m_G(H) = \|k\|_{L_1(m_G)} \leq 2Mm_G(\text{supp } f_{\mathbb{Z}}),$$

which gives

$$\|z\|_{\ell_1(G/H)} \leq \exp(O(M^4 \log^8 2M + M^3 \log \eta^{-1}(\log 2 \log 2\eta^{-1}))).$$

It remains to put $g := f * \nu * \tilde{\nu}$ and note that $g_{\mathbb{Z}} = k$ has the required properties. Moreover, since k is not identically 0 we see that

$$\|g\|_{A(G)} \geq \|g\|_{L_{\infty}(G)} \geq \|k\|_{L_{\infty}(G)} - (\epsilon + \eta) \geq 1 - \epsilon - \eta,$$

and

$$\begin{aligned} \|f\|_{A(G)} &= \sum_{\gamma} |\hat{f}(\gamma)| \\ &= \sum_{\gamma} |\hat{f}(\gamma)| (1 - |\hat{\nu}(\gamma)|^2) + \sum_{\gamma} |\hat{f}(\gamma)| |\hat{\nu}(\gamma)|^2 \\ &= \|f - f * \nu * \tilde{\nu}\|_{A(G)} + \|f * \nu * \tilde{\nu}\|_{A(G)} \geq \|f - f * \nu * \tilde{\nu}\|_{A(G)} - (1 - (\epsilon + \eta)), \end{aligned}$$

from which we get the final inequality. \square

We are now in a position to prove our main result.

Proof of Theorem 10.1. If $f \equiv 0$ then we are done; if not let $M := \|f\|_{A(G)} \geq 1$. We produce a sequence of functions f_i , reals ϵ_{i+1} , subgroups H_{i+1} , and functions $z_{i+1} : G/H_{i+1} \rightarrow \mathbb{Z}$ such that

- (i) $\epsilon_i := 2^i \epsilon + 4^{i-2M-4} \exp(-C_{\text{MÉL}} M)$;
- (ii) f_i is ϵ_i -almost integer-valued;
- (iii) $\|f_{i+1}\|_{A(G)} \leq \|f_i\|_{A(G)} - \frac{1}{2}$;
- (iv) $(f_{i+1} - f_i)_{\mathbb{Z}} = \sum_{W \in G/H_{i+1}} z_{i+1}(W) 1_W$.

Set $f_0 := f$ and note that since f is ϵ -almost integer-valued it is certainly ϵ_0 -almost integer-valued. At stage $i \leq 2M+1$ apply Lemma 10.2 with parameter $\eta := 4^{-2M-3} \exp(-C_{\text{MÉL}} M)$, which is possible (provided ϵ is sufficiently small) since

$$\epsilon_i \leq 2^{2M+1} \epsilon + 4^{2M+1-2M-4} \exp(-C_{\text{MÉL}} M) \leq \min\{\exp(-C_{\text{MÉL}} M), 2^{-3}\}.$$

Either $(f_i)_{\mathbb{Z}} \equiv 0$ and we terminate the iteration or we get a function f_{i+1} , a group H_{i+1} and a function $z_{i+1} : G/H_{i+1} \rightarrow \mathbb{Z}$, with

$$(f_{i+1} - f_i)_{\mathbb{Z}} = \sum_{W \in G/H_{i+1}} z_{i+1}(W) 1_W \text{ and } \|z_{i+1}\|_{\ell_1(G/H_{i+1})} \leq \exp(O(M^4 \log^8 2M))$$

such that

$$\|f_{i+1}\| \leq \|f_i\|_{A(G)} - (\epsilon_i + \eta_i) \leq \|f_i\|_{A(G)} - \frac{1}{2}.$$

Since f_i is ϵ_i -almost integer-valued it follows that f_{i+1} is $(2\epsilon_i + \eta_i)$ -almost integer-valued. But

$$\begin{aligned} (2\epsilon_i + \eta) &\leq 2(2^i \epsilon + 4^{i-2M-3} \exp(-C_{\text{MÉL}} M) + 4^{-2M-3} \exp(-C_{\text{MÉL}} M)) \\ &\leq 2^{i+1} \epsilon + 4^{i+1-2M-3} \exp(-C_{\text{MÉL}} M), \end{aligned}$$

and so f_{i+1} is ϵ_{i+1} -almost integer-valued.

Of course this cannot repeat more than $2M$ times and so it follow that there is some $i \leq 2M+1$ such that $(f_i)_{\mathbb{Z}} \equiv 0$. Of course,

$$\begin{aligned} &\left\| f - (f_i)_{\mathbb{Z}} - \sum_{j=0}^{i-1} (f_{j+1} - f_j)_{\mathbb{Z}} \right\|_{L_{\infty}(G)} \\ &\leq \left\| f - f_i - \sum_{j=0}^{i-1} (f_{j+1} - f_j) \right\|_{L_{\infty}(G)} \\ &\quad + \|f_i - (f_i)_{\mathbb{Z}}\|_{L_{\infty}(G)} + \sum_{j=0}^{i-1} \|(f_{j+1} - f_j) - (f_{j+1} - f_j)_{\mathbb{Z}}\|_{L_{\infty}(G)} \\ &= 0 + \epsilon_i + \sum_{j=0}^{i-1} (\epsilon_{j+1} + \epsilon_j) \leq \exp(O(M)) \epsilon + \frac{1}{4} < \frac{1}{2}, \end{aligned}$$

provided ϵ is sufficiently small. The result follows since $f_{\mathbb{Z}}$ is uniquely defined in this case. \square

11. CONCLUDING REMARKS

Cohen's idempotent theorem [Coh60] is a qualitative version of our main result. It can be combined with our main theorem in the same way as [GS08, Theorem 1.3] was used to yield [GS08, Theorem 1.3] (see [GS08, Appendix A] for details).

Recall that if G is a locally compact Abelian group then we can define \hat{G} to be the (locally compact Abelian group) of continuous homomorphisms $G \rightarrow S^1$. (See [Rud90, §1.2.1].) Then we say f is an element of $B(G)$ if there is a measure $\mu \in M(\hat{G})$ such that

$$f(x) = \int \gamma(x) d\mu(\gamma) \text{ for all } x \in G.$$

We write $\|f\|_{B(G)} := \|\mu\|$ and refer the reader to [Rud90, §1.5.1] for details, but in particular if G is finite then $\|f\|_{A(G)} = \|f\|_{B(G)}$.

Theorem 11.1. *Suppose that G is a locally compact Abelian group and $f \in B(G)$ is integer-valued. Then, writing $\mathcal{W}(G) := \{G/H : H \leq G \text{ is closed.}\}$, there is some $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ such that*

$$f = \sum_{W \in \mathcal{W}(G)} z(W) 1_W \text{ and } \|z\|_{\ell_1(\mathcal{W}(G))} \leq \exp(O(\|f\|_{B(G)}^4 \log^8 2 \|f\|_{B(G)})).$$

It is also worth making a couple of remarks on specific classes of groups. If $G = \mathbb{Z}$ it is known from work of Konyagin [Kon81] and McGehee, Pigno and Smith [MPS81] that we can do better and, in particular, we have the following rewritten in our language.

Theorem 11.2. *Suppose that $G = \mathbb{Z}$ and $f \in \ell_1(G) \cap B(G)$ is integer-valued. Then there is some $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ such that*

$$f = \sum_{W \in \mathcal{W}(G)} z(W) 1_W \text{ and } \|z\|_{\ell_1(\mathcal{W}(G))} \leq \exp(O(\|f\|_{B(G)})).$$

This is best possible as can be seen by taking f to be the indicator function of symmetric interval around 0 of length N . The Fourier transform of f is a Dirichlet kernel and from this it is easy to show that $\|f\|_{B(G)} = O(\log N)$. The only finite subgroup of \mathbb{Z} is $\{0\}$ whence one requires any suitable function z to have

$$\|z\|_{\ell_1(\mathcal{W}(G))} = \exp(\Omega(\|f\|_{B(G)})).$$

If $G = \mathbb{Z}/p\mathbb{Z}$ for p a prime then there are a range of results by Konyagin and various authors. In particular the following is an easy consequence of [GK09, Theorem 1.3].

Theorem 11.3. *Suppose that $G = \mathbb{Z}/p\mathbb{Z}$ and $A \subset G$ has $m_G(A) = \alpha \in (0, \frac{1}{2}]$. Then*

$$\|1_A\|_{A(G)} = \alpha \log^{\frac{1}{3}-o(1)} p.$$

The above bound becomes weaker as A gets smaller. Konyagin and Shkredov [KS15, KS16] have the following results to deal with this.

Theorem 11.4 ([KS15, Theorem 13]). *Suppose that $G = \mathbb{Z}/p\mathbb{Z}$ and $A \subset G$ has size $2 \leq |A| \leq \exp((\log p / \log \log p)^{1/3})$. Then*

$$\|1_A\|_{A(G)} = \Omega(\log |A|).$$

Theorem 11.5 ([KS16, Theorem 3]). *Suppose that $G = \mathbb{Z}/p\mathbb{Z}$ and $A \subset G$ has density α with $\exp((\log p / \log \log p)^{1/3}) \leq |A| \leq p/3$. Then*

$$\|1_A\|_{A(G)} = \Omega(\log \alpha^{-1})^{1/3-o(1)}.$$

In $\mathbb{Z}/p\mathbb{Z}$ there are no non-trivial subgroups and so these three results can be combined to give the following.

Theorem 11.6 (Green-Konyagin-Shkredov). *Suppose that $G = \mathbb{Z}/p\mathbb{Z}$ and $A \subset G$ has $\|1_A\|_{A(G)} \leq M$ for some $M \geq 1$. Then there is some $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ such that*

$$1_A = \sum_{W \in \mathcal{W}(G)} z(W)1_W \text{ and } \|z\|_{\ell_1(\mathcal{W}(G))} \leq \exp(\exp(M^{3+o(1)})).$$

Note that this is already a strengthening of the main result of [GS08] in the particular case of groups of prime order. In fact, however, Konyagin and Shkredov's results are much sharper if one takes A to be sparse. For example, they combine to give the following.

Theorem 11.7 (Konyagin-Shkredov). *Suppose that $G = \mathbb{Z}/p\mathbb{Z}$ and $A \subset G$ has $\|1_A\|_{A(G)} \leq M$ for some $M \geq 1$ and $|A| \leq p^{9/10}$. Then there is some $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ such that*

$$1_A = \sum_{W \in \mathcal{W}(G)} z(W)1_W \text{ and } \|z\|_{\ell_1(\mathcal{W}(G))} \leq \exp(M^{3+o(1)}).$$

This is stronger than our main theorem in this particular case of small sets in groups of prime order.

At the other end of the scale from groups of prime order are the dyadic groups, which have a rich subgroup structure. The arguments used to prove Theorem 10.1 simplify somewhat if $G = \mathbb{F}_2^n$ and if followed through they lead to the next theorem.

Theorem 11.8. *Suppose that $G = \mathbb{F}_2^n$ and $f : G \rightarrow \mathbb{Z}$ has $\|f\|_{A(G)} \leq M$. Then there is some $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ such that*

$$f = \sum_{W \in \mathcal{W}(G)} z(W)1_W \text{ and } \|z\|_{\ell_1(\mathcal{W}(G))} \leq \exp(M^{3+o(1)}).$$

However, this can be improved in a different way. Shpilka, Tal and lee Volk establish the following result in [STV14].

Theorem 11.9 ([STV14, Theorem 1.2]). *Suppose that $G = \mathbb{F}_2^n$ and $A \subset G$ and $\|1_A\|_{A(G)} \leq M$. Then there is some $z : \mathcal{W}(G) \rightarrow \mathbb{Z}$ such that*

$$1_A = \sum_{W \in \mathcal{W}(G)} z(W)1_W \text{ and } \|z\|_{\ell_1(\mathcal{W}(G))} \leq \exp(O(M^2 + M \log n)).$$

While our aim is to avoid any sort of n dependence, it is worth noting that in the above theorem it is really rather mild.

For this class of groups arithmetic progressions are no longer a limiting example and it might be that the bound on $\|z\|_{\ell_1(\mathcal{W}(G))}$ can be polynomial in M . Some efforts in this direction for particular classes of function can be found in work of Tsang, Wong, Xie and Zhang, in particular [TWXZ13, Corollary 7].
